(54) Title: ADDRESSABLE PROTEIN ARRAYS

(57) Abstract

Disclosed herein are arrays of nucleic acid-protein fusions which are immobilized to a solid surface through capture probes which include a non-nucleosidic spacer group and an oligonucleotide sequence to which the fusion (such as an RNA-protein fusion) is bound. Also disclosed herein are solid supports on which these arrays are immobilized as well as methods for their preparation and use (for example, for screening for protein-compound interactions such as protein-therapeutic compound interactions).

ADDRESSABLE PROTEIN ARRAYS

Background of the Invention

5 The invention relates to fixed arrays of nucleic acid-protein fusions and, in particular, RNA-protein fusions, on solid supports.

Certain macromolecules, such as proteins, are known to interact specifically with other molecules based on the three-dimensional shapes and electronic distributions of those molecules. For example, proteins interact
10 selectively with other proteins, with nucleic acids, and with small-molecules. Modern pharmaceutical research relies on the study of these interactions; the development of new drugs depends on the discovery of compounds that bind specifically to biologically important molecules.

The discovery of a single drug candidate can require the screening of
15 thousands of compounds. It is therefore important to be able to screen large numbers of compounds rapidly and efficiently. One method for screening a large number of compounds is to fix possible binding partners, such as proteins, to a solid support.

It is difficult to prepare arrays of isolated proteins on solid supports,
20 however, for a variety of reasons. First of all, proteins cannot always be easily attached to the planar surfaces traditionally used to make other fixed arrays, such as nucleic acid microchips. More importantly, because proteins can interact with the functional groups on the surfaces of these supports, the proximity of the protein to the surface can lead to disruption of the protein
25 structure.

Summary of the Invention

In general, the invention features a solid support including an array of immobilized capture probes; each of the capture probes includes a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound (for example, hybridized or covalently bound). In preferred embodiments, the nucleic acid-protein fusion is an RNA-protein fusion, and the protein component is encoded by the nucleic acid (for example, the RNA). The spacer group can include a polyalkylene oxide, for example, polyethylene oxide. A preferred spacer group includes hexaethylene oxide.

10 The capture probe may also include a photocleavable linker.
The oligonucleotide sequence can include a modified base, such as 5-propyne pyrimidine. It can also include an internucleotide analog (such as 3'-phosphoramidate) or a carbohydrate modification (such as a 2'-O-methyl group). The nucleic acid-protein fusion can include a hybridization tag sequence. The hybridization tag sequence can also include a modified base, an internucleotide analog, or a carbohydrate modification.

15 In a preferred embodiment, the capture probe further includes a reactive moiety (for example, a nucleophilic group), such as a primary amino group. In another preferred embodiment, the nucleic acid-protein fusion is covalently linked to the capture probe (for example, by photo-crosslinking); in one preferred approach, this is accomplished by including one or more psoralen moieties in the capture probe or in the capture probe-fusion hybridization reaction mixture. A preferred solid support is a glass or silica-based chip.

20 In a related aspect, the invention features a solid support including an array of immobilized capture probes; each of the capture probes is attached to the surface of the solid support through a non-nucleosidic spacer group, and

-3-

each of the capture probes includes an oligonucleotide sequence to which a nucleic acid-protein fusion (for example, an RNA-protein fusion) is bound (for example, hybridized or covalently bound).

In another related aspect, the invention features a solid support
5 including an array of immobilized capture probes; each of the capture probes includes a non-nucleosidic spacer group and an oligonucleotide sequence to which a ribosome display particle is bound (for example, hybridized or covalently bound).

In yet another related aspect, the invention features a method for
10 preparing a solid support. The method includes the steps of: (a) preparing a capture probe by linking a spacer group to an oligonucleotide sequence; (b) attaching the capture probe to the solid support; and (c) binding (for example, hybridizing or covalently binding) a nucleic acid-protein fusion (for example, an RNA-protein fusion) to the capture probe.

15 The invention also features a second general method for preparing a solid support. This method includes the steps of: (a) attaching a spacer group to a surface of the solid support; (b) attaching a bifunctional linker to the spacer group; (c) attaching a capture probe to the bifunctional linker; and (d) binding (for example, hybridizing or covalently binding) a nucleic acid-protein fusion
20 (for example, an RNA-protein fusion) to the capture probe.

In a second aspect, the invention features a method for detecting an interaction between a protein and a compound. The method includes the steps of: (a) providing a solid support including an array of immobilized capture probes, where each of the capture probes includes a non-nucleosidic spacer
25 group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound (for example, hybridized or covalently bound); (b) contacting the solid support with a candidate compound under conditions which allow an

interaction between the protein portion of the nucleic acid-protein fusion and the compound; and (c) analyzing the solid support for the presence of the compound as an indication of an interaction between the protein and the compound.

5 Alternatively, the invention features another method for detecting an interaction between a protein and a compound; this method involves the steps of: (a) providing a population of nucleic acid-protein fusions; (b) contacting the population of nucleic acid-protein fusions with a candidate compound under conditions which allow an interaction between the protein portion of the

10 nucleic acid-protein fusion and the compound; (c) contacting the product of step (b) with a solid support that includes an array of immobilized capture probes, each of the capture probes including a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion binds (for example, hybridizes or covalently binds); and (d) analyzing the solid

15 support for the presence of the compound as an indication of an interaction between the protein and the compound.

In a preferred embodiment of each of the above methods, the nucleic acid-protein fusion is an RNA-protein fusion. In another preferred embodiment, the compound is labeled. Compounds that can be screened using

20 these methods include, without limitation, proteins, drugs, therapeutics, enzymes, and nucleic acids.

In a third aspect, the invention features an array (for example, an addressable array) of nucleic acid-protein fusions including at least 10^2 different fusions/cm². Preferably, the nucleic acid-protein fusions are RNA-protein fusions, and the array includes at least 10^4 different fusions/cm².

In a related aspect, the invention features a method for generating an addressable array of molecules. The method involves: (a) providing a solid

-5-

support on which an array of nucleic acid molecules is immobilized; (b) contacting the solid support with a population of addressable molecules; and (c) allowing the addressable molecules to orient themselves on the solid support by sequence-dependent recognition and binding of the immobilized nucleic acid
5 molecules.

In preferred embodiments of this method, the addressable array of molecules is an array of nucleic acid-protein fusions (for example, an array of RNA-protein fusions); the addressable molecules orient themselves on the solid support by base pairing (for example, hybridization) with the immobilized
10 nucleic acid molecules; the solid support is a glass or silica-based chip; and the nucleic acid molecules immobilized on the solid support are capture probes, each including a non-nucleosidic spacer group and an oligonucleotide sequence to which the addressable molecule binds.

As used herein, by an "array" is meant a fixed pattern of
15 immobilized objects on a solid surface or membrane. Typically, the array is made up of nucleic acid-protein fusion molecules (for example, RNA-protein fusion molecules) bound to capture nucleic acid sequences which themselves are immobilized on the solid surface or membrane. The array preferably includes at least 10^2 , more preferably at least 10^3 , and most preferably at least
20 10^4 different fusions, and these fusions are preferably arrayed on a 125 x 80 mm, and more preferably on a 10 x 10 mm, surface. By an "addressable array" is meant that the locations, or addresses, on the solid support of the members of the array (for example, the nucleic acid-protein fusions) are known; the members of the array are referred to as "addressable molecules" and are
25 utilized in methods for screening for subsequent molecular interactions (for example, for screening for interactions between the addressable nucleic acid-protein fusions and candidate therapeutics).

-6-

By "nucleic acid-protein fusion" is meant a nucleic acid covalently bound to a protein. By "nucleic acid" is meant any two or more covalently bonded nucleotides or nucleotide analogs or derivatives. As used herein, this term includes, without limitation, DNA, RNA, and PNA. By "protein" is
5 meant any two or more amino acids, or amino acid analogs or derivatives, joined by peptide or peptoid bond(s), regardless of length or post-translational modification. As used herein, this term includes, without limitation, proteins, peptides, and polypeptides.

By "hybridization tag" is meant a non-coding oligonucleotide
10 sequence that differs sufficiently in sequence from other nucleic acid sequences in a given population or reaction mixture that significant cross-hybridization does not occur. When multiple hybridization tags are utilized in a single reaction mixture, these tags also preferably differ in sequence from one another such that each has a unique binding partner under the conditions employed.
15 By a "population" is meant more than one molecule.

By a "solid support" is meant any solid surface including, without limitation, any chip (for example, silica-based, glass, or gold chip), glass slide, membrane, bead, solid particle (for example, agarose, sepharose, or magnetic bead), column (or column material), test tube, or microtiter dish.

20 Brief Description of the Drawings

Figure 1 is a drawing showing the silylation of a glass surface, the derivatization of the resulting amino groups, and the attachment of a capture probe to the modified surface.

25 Figure 2 is a drawing illustrating a capture probe containing a non-nucleosidic spacer group and a reactive moiety.

Figure 3 is a schematic diagram of the layout of the FLAG and

-7-

HA11 fusion chip capture probes utilized in Figures 4 and 5. In this Figure, t7, tag, au1, au5, flag, ha1, irs, and kt3 represent the capture probes CPt7 (positive control), CPtag (positive control), CPau1 (negative control), CPau5 (negative control), CPflag, CPha11, CPIrs (negative control), and CPkt3 (negative control), respectively.

5 Figure 4 is a phosphorimage demonstrating hybridization of nucleic acid-protein fusions (FLAG and HA11) to capture probes immobilized on a chip.

Figure 5 is a fluorimage demonstrating hybridization of nucleic acid-10 protein fusions (FLAG and HA11) to capture probes immobilized on a chip and subsequent recognition with anti-HA11 monoclonal antibodies.

Figure 6 is a schematic diagram of the layout of the Myc fusion chip capture probes utilized in Figures 7 and 8. In this Figure, capture probes CP01, CP33, CP80, CP125, CPmm, and CPns (described herein) were arranged on the 15 chip as follows: CP01 at locations A1, B1, C1, A4, B4, and C4; CP33 at locations D1, E1, F1, D4, E4, and F4; CP80 at locations A2, B2, C2, A5, B5, and C5; CP125 at locations D2, E2, F2, D5, E5, and F5; CPmm at locations A3, B3, C3, A6, B6, and C6; and CPns at locations D3, E3, F3, D6, E6, and F6.

Figure 7 is a phosphorimage demonstrating hybridization of nucleic acid-protein fusions (Myc) to capture probes immobilized on a chip.

Figure 8 is a fluorimage demonstrating hybridization of nucleic acid-protein fusions (Myc) to capture probes immobilized on a chip and subsequent 20 recognition with anti-Myc monoclonal antibodies.

Description of the Preferred Embodiments

25 The invention features support-based, addressable arrays of proteins, and methods for preparing and using these arrays. The arrays are prepared by

-8-

fixing oligonucleotide sequences, the capture probes (or capture oligos), to a support in a defined array. The capture probes are then used to bind nucleic acid-protein fusions, such as RNA-protein fusions. Such binding may occur through base pairing (for example, through Watson-Crick base pairing, pseudo
5 Watson-Crick base pairing involving modified bases, or Hoogsteen base pairing) between the nucleic acid component of the fusion and a complementary capture probe, or may occur through any other type of sequence-dependent recognition and binding of the capture probe (including, without limitation, polyamide-mediated nucleic acid groove binding or specific
10 binding by nucleic acid-binding proteins such as transcription factors). The result of the binding interactions between the fusions and the capture probes is a defined, addressable array of proteins attached to a solid support.

A variety of materials can be used as the solid support. Examples of such materials include polymers (e.g., plastics), aminated surfaces, gold coated
15 surfaces, nylon membranes, polyacrylamide pads deposited on solid surfaces, silicon, silicon-glass (e.g., microchips), silicon wafers, and glass (e.g., microscope slides). Microchips, and particularly glass microchips, represent a preferred solid support surface.

If the surface is not already aminated, it can be modified to provide a
20 layer of amino groups. For example, a glass microscope slide can be treated with a silylating agent such as trialkoxyaminosilane to provide a surface of primary amino groups that exists as a monolayer or 3-8 molecular layers. This reaction is illustrated in Figure 1. The silane-treated surface is then derivatized with a homobifunctional or heterobifunctional linker that permits the
25 attachment of oligonucleotides at discrete positions. Phenylene 1,4-diisothiocyanate is a useful homobifunctional linker; amino-surfaces derivatized with this reagent have isothiocyanate functionalities that are

-9-

available to covalently react with the primary amino groups on the termini of oligonucleotides to form stable thiourea bonds, as shown in Figure 1.

The capture probes, i.e., the oligonucleotide sequences that are to be attached to the surface, are selected from the reverse-complements of the

5 nucleic acid components of the nucleic acid-protein fusions (the targets).

Capture probes preferably have between 5 and 30 nucleotide units, and more preferably have about 20 nucleotide units. Considerations for the selection of the exact sequence for a particular capture probe include melting temperature (T_m), interference from competing target sequences, and potential secondary

10 structure in the target sequence. Ideally, each unique capture probe has the same T_m, i.e., they are isoenergetic, so a single hybridization and washing temperature can be used successfully for all capture-target pairs. Commercially available computer programs (e.g., Oligo 4.0) can be used to help identify sets of capture probes with similar thermodynamic properties based on nearest

15 neighbor treatments.

The capture probes are modified before they are attached to the surface. One or more non-nucleosidic spacers, such as polyethylene oxide, are added to the terminus of the oligo. Preferably, 1-20 spacers and, most preferably, 4 spacers are utilized. These spacers may be added to either the 5'

20 or preferably the 3' end of the oligonucleotide. A nucleophilic moiety is then attached to the spacer group. The result is a derivatized capture probe, as shown in Figure 2. A preferred spacer monomer includes hexaethylene oxide.

Non-nucleosidic spacers are preferred over nucleosidic spacers, such as poly-T, because non-nucleosidic spacers have greater flexibility. In addition, their physical properties can be tailored relatively easily, and it is possible to minimize specific and non-specific nucleic acid interactions.

The spacers provide physical separation between the oligonucleotide

-10-

and the solid surface and prevent interaction of the proteins with the support surface. This separation is important to ensure effective hybridization between the support-bound capture probe and the nucleic acid-protein fusion. In addition, the separation helps to minimize denaturation of the protein; the 5 proteins are therefore able to adopt their native folded structures and remain functional.

Alternatively, the spacer groups can be attached directly to the solid support surface, instead of to the capture probes. For example, the spacer group can be attached to the amino groups on the surface. The bifunctional 10 linker can then be attached to the other end of the spacer group.

In addition to spacer groups, the capture probes may contain modifications that improve their hybridization properties and mismatch discrimination. For example, they may contain base analogs, such as 5-propyne pyrimidines, internucleotide analogues such as peptide nucleic acids 15 (PNA), in which the bases are connected by peptide-like linkages, or carbohydrate modifications.

The capture probes are suspended in an aqueous alkaline solution, then applied to defined positions of the support surface; the nucleophilic moieties at the termini of the capture probes react with the active sites of the 20 bifunctional linkers to form covalent bonds. The density of the capture probes can be controlled by adjusting reaction time and oligo concentration. Alternatively, the density can be controlled by doping the solution with capture oligos that lack nucleophilic moieties or doping with simple organic compounds that possess amine functional groups.

25 The capture probes can be applied using liquid deposition techniques, such as inkjet delivery, robotic quill delivery or spotting, and other similar deposition methods. They can also be applied using manual methods,

such as pipetting. The feature sizes of the capture probes can range from one square micron (e.g., when robotic techniques are used) to one square millimeter (e.g., when a 0.2 microliter pipette is used). The result of the application of the capture probes is a defined, regular array of nucleic acid sequences.

5

After a sufficient reaction time, the excess capture probe is washed away, and the remaining unreacted isothiocyanate groups are blocked off. Dilute ammonia can be used as the blocking agent, resulting in a surface of phenyl thiourea groups. Blocking agents can also be selected to modify the 10 surface energy, i.e., the hydrophobicity of the solid support surface. The hydrophobicity of the solid support surface is important because it affects the background signal level and the extent of unwanted interaction of the protein portion of a nucleic acid-protein fusion with the surface. Examples of blocking agents that modify hydrophobicity are methylamine, amino alcohols, and 15 suitable amino-containing polyethylene oxide moieties.

10

15

20

25

Non-covalent blocking agents can also be used to further minimize non-specific interactions between the fusion and the solid support (e.g., glass) surface. Examples of such blocking agents include non-specific proteins such as BSA or casein, or similar commercially available blocking reagent formulations marketed for use with membranes.

The capture probes arrayed on the surface of the solid support are then bound (for example, by hybridization) to nucleic acid-protein fusions, such as RNA-protein fusions. A solution containing the mixture of fusions is adjusted to an appropriate salt concentration, applied to the surface, and 18

-12-

(Sigma Chemical Co.) at concentrations of about 0.02% to about 1.0%; it may also include non-specific proteins, such as BSA.

The experimental variables of salt concentration, temperature, and hybridization time are a function of the capture oligo design. A preferred range 5 for the salt concentration is 25 mM to 2 M, with a concentration of about 750 mM being especially preferred. A preferred temperature range is from 5°C to 70°C, with 30°C being especially preferred. Preferred reaction times can be from 1 to 24 hours, with 3 hours being especially preferred. The variables for each experiment are determined empirically by standard methods. The 10 hybridization step can be performed in a simple chamber device that constrains the liquid sample and prevents evaporation.

When RNA-protein fusions are utilized as addressable arrays, the solution may also contain one or more components to suppress nuclease degradation of the RNA moiety. Preferred additions include (a) metal chelators 15 (e.g., EDTA or EGTA) at concentrations of between 1 - 10 mM, (b) placental RNase inhibitor protein (Promega) at concentrations of between 0.1 - 1 Unit/μl; and (c) Anti-RNase protein (Ambion) at concentrations of between 0.1 - 1 Unit/μl. A separate strategy to specifically suppress 5'-exonuclease degradation involves capping the 5'-terminus of the fusion RNA with a binding 20 molecule. The capping strategy may be used in conjunction with one or more of the components listed above. In one particular capping approach, a native or analog (e.g., PNA) nucleic acid sequence complementary to the 5'-terminus of the fusion RNA is added to generate a stable duplex at the 5'-end. The complementary sequence is preferably between 10 - 50 bases in length, and 25 most preferably about 20 bases in length. This added nucleic acid sequence may also contain pendant groove-binding, intercalating, or cross-linking moieties. Alternatively, native or analog nucleic acid sequences may be added

-13-

that form stable intermolecular hairpin, tetraloop, or pseudoknot secondary structures with the 5'-terminus of the RNA. In the latter case, these nucleic acids are preferably about 20 - 100 bases in length, with about 35 bases being especially preferred.

5 To the extent possible, the mixture of nucleic acid-protein fusions should be free of un-fused nucleic acids. Un-fused nucleic acids that are complementary to the capture probes will compete with the fusions for binding and will limit the amount of a given protein that can be displayed on the solid support. Preferably, at least 1% of the nucleic acid (for example, the RNA
10 message) is fused to protein.

Unique non-coding regions can be incorporated into the nucleic acid component of the fusion for the specific purpose of being "captured" by the capture probe; these non-coding regions are referred to as "hybridization tag sequences." The hybridization tag sequences may include the same analogue
15 units as are described above for the capture probes. In some cases, both the capture probe and the tag sequences can be modified so they hybridize preferentially with each other, thereby minimizing interference from the coding fusion sequences.

Upon completion of the binding step, unbound nucleic acid-protein
20 fusion is washed away with a buffer that has a higher stringency and a lower salt concentration than that used for the hybridization step. Again, the optimal buffer composition is determined empirically by standard methods. What remains upon completion of washing is an addressable array of proteins on the solid surface, attached via sequence-dependent recognition between the nucleic
25 acid component of the fusion and the surface-bound capture oligo. The position of each protein is defined, because each fusion corresponds to the complementary capture probe.

-14-

In addition, if desired, the nucleic acid component of the fusion may be covalently linked to a part of the solid support, the linker, or the capture probe. Such covalently linked fusions provide particularly robust and versatile addressable arrays that may be used, for example, in the screening methods 5 described herein. Covalently linked fusion arrays may be generated by any standard approach. According to one general technique, the fusions are addressed to specific locations on a solid surface via hybridization with corresponding capture probes, and a chemical cross-linking or attachment reaction is triggered to fix the location of the fusions on the solid support. One 10 method to achieve such a covalent link involves functionalizing the DNA capture oligos during chemical synthesis with one or more pendant psoralen moieties, preferably positioned near adenine bases. After hybridizing the nucleic acid-protein fusion (for example, the RNA-protein fusion) to the support-bound capture oligos, the surface is exposed to long-wavelength UV 15 light (for example, at 350 nm). Light of this wavelength triggers a photoreaction between psoralen and an adjacent thymidine or uridine base in the duplex region, forming a cyclobutane linkage and permanently attaching the fusion to the solid support. Alternatively, psoralen itself (i.e., not linked to a capture probe) may be included in the hybridization solution or in a 20 subsequent separate solution. The psoralen molecule intercalates between bases in double-stranded regions. Upon irradiation with long-wavelength UV light, the intercalated psoralen cross-links with thymidine or uridine bases (intrastrand and interstrand) in a bifunctional mode, forming covalent links between the capture probe and the nucleic acid component of the fusion. Other 25 reactive, cross-linking reagents may also be used in place of psoralen in combination with triggering conditions appropriate for those reagents.

Ordered, addressable arrays of peptide fragments can also be

-15-

prepared. To prepare these arrays, the fusion library is generated from short synthetic DNA sequences or fragments of cDNAs or genomic DNAs. In another variation, ribosome display particles, such as those described in Gold et al., WO 93/03172, can be hybridized to the solid support to generate the protein array. Again, these particles are immobilized on the solid support through a hybridization reaction between the capture oligo and the protein-coding RNA.

Use

The addressable protein arrays of the present invention have many uses. For example, a library of proteins can be displayed on a support, such as 10 a microchip. This microchip can then be used to identify previously unknown protein-protein interactions. A probe protein can be detectably labeled, for example, with a radioisotope, chromophore, fluorophore, or chemiluminescent species, then incubated with the microchip. After the excess probe protein is washed away, the chip surface is analyzed for signal from the label. Detection 15 of a signal indicates interaction of the labeled protein with one or more unique members of the protein library. The identity of proteins that are able to bind to the probe protein can then be determined from the location of the spots on the chip that become labeled due to binding of the probe. The same approach can also be used to screen protein libraries for protein-ligand interactions and 20 protein-nucleic acid interactions.

Other methods can be used to detect protein-protein, protein-ligand, or protein-nucleic acid interactions. For example, when the solid surface used to form the protein array is a gold layer, surface plasmon resonance (SPR) can be used to detect mass changes at the surface. When gold surfaces are 25 employed, the reactive moiety on the oligonucleotide capture probe is a thiol group (rather than an amino group) and the gold surface need not be

-16-

functionalized to achieve capture probe attachment. Mass spectrometry (especially, Maldi-ToF) can also be used to analyze species bound to unique members of the protein library.

Another application of protein arrays is the rapid determination of
5 proteins that are chemically modified through the action of modifying enzymes such as protein kinases, acyl transferases, and methyl transferases. By incubating the protein array with the enzyme of interest and a radioactively labeled substrate, followed by washing and autoradiography, the location and hence the identity of those proteins that are substrates for the modifying
10 enzyme may be readily determined. Further localization of the modification sites can be achieved using ordered displays of fragments of these proteins.

The protein arrays can also be used to identify the unknown protein targets of therapeutically active compounds. For example, a therapeutic compound may be applied to a protein array derived from cellular RNA.
15 Detection of the captured therapeutic compound, either through its bound label or directly (for example, by mass spectrometry or surface plasmon resonance) reveals the compound's binding partner or partners. In addition, arrays can also be used in the development of protein-based diagnostics. For example, a solid support containing a variety of proteins associated with various illnesses can be
20 prepared. A single patient sample, which might contain one or more proteins whose interactions with the support-bound proteins would be indicative of certain illnesses, can then be contacted with the support. Thus, a single sample can be used to simultaneously detect the presence of several conditions, or to distinguish between conditions. Alternatively, addressable arrays may be used
25 to quantify target molecules in a sample. In one particular example, addressable arrays of single chain antibodies or antibody mimics may be used for quantifying a target protein (or proteins) in a biological sample. The arrays

-17-

can also be used in the emerging fields of proteomics and functional genomics.

The specific fusions that are identified as binding specifically to a probe molecule can be removed from the support surface. In one method, the fusion is released by disrupting hybridization with the capture probe. In one 5 particular approach, the specified fusion is physically separated from the rest of the fusions, then treated with a denaturing agent, such as a chemical reagent or heat, to disrupt the base pairing with the capture oligo. The liberated fusion is then recovered from the solution.

Alternatively, the entire capture probe can be detached. During solid 10 support preparation, a light-sensitive linker can be used to attach the capture probe to the solid surface. Following identification of the active fusion, a laser beam of the appropriate wavelength can be used to cleave the linker, thus releasing the desired fusion. Following release from the surface by any of the above methods, the fusion can be specifically recovered and manipulated, for 15 example, using PCR, and further characterized.

There now follow particular examples of the preparation of protein arrays according to the invention. These examples are provided for the purpose of illustrating the invention, and should not be construed as limiting.

Example 1: Silylation of a Glass Surface

20 Select grade, low-iron content, pre-cleaned 1 x 3 inch glass microscope slides (VWR Scientific) are prepared by heating with 1 M hydrochloric or nitric acid for 30 minutes at 70°C. The slides are then subjected to three 5-minutes washes, using fresh distilled water for each wash. A 1% solution of aminopropyltrimethoxysilane (Gelest, Inc.) in 95% 25 acetone/5% water is prepared and allowed to hydrolyze for at least five minutes. The glass slides are immersed in the hydrolyzed silane solution for

-18-

2-20 minutes with gentle agitation. Excess silane is removed by subjecting the slides to ten 5-minute washes, using fresh portions of 95% acetone/5% water for each wash, using gentle agitation. The slides are then cured by heating at 110°C for 20-45 minutes.

5 Example 2: Derivatization with a Homobifunctional Linker

Silane treated slides from Example 1 are immersed in a freshly prepared 0.2% solution of phenylene 1,4-diisothiocyanate (Aldrich Chemical Co.) in 90% DMF/10% pyridine for two hours, with gentle agitation. The slides are washed sequentially with 90% DMF/10% pyridine, methanol, and 10 acetone. After air drying, the functionalized slides are stored at 0°C in a vacuum desiccator over anhydrous calcium sulfate.

Example 3: Synthesis of Capture Probes

Oligonucleotides are chemically synthesized in the 3'→5' direction by coupling standard phosphoramidite monomers with an automated DNA 15 synthesizer. Typically, 500 angstrom controlled-pore glass supports are used at the 0.2 micromole scale. After the desired probe sequence has been assembled (using A, G, C, and T monomers), hexaethylene oxide phosphoramidite monomer (Glen Research) is added to the 5' terminus. The coupling wait time is extended to 15 minutes by modifying the synthesizer program. Additional 20 hexaethylene oxide monomer units are added in the same way. C-6 Amino phosphoramidite (Glen Research) is then added to the 5' terminus; the coupling wait time is again extended to 15 minutes. The acetic anhydride capping step and the final acidic detritylation step are eliminated. Capture probe sequences are cleaved from the solid support and deprotected with ammonium hydroxide, 25 concentrated to dryness, precipitated in ethanol, and purified by reverse-phase

HPLC using an acetonitrile gradient in triethylammonium acetate buffer.

Example 4: Attachment of Capture Probes

The purified, amine-labeled capture probes from Example 3 are adjusted to a concentration of 500 micromolar in 100 mM sodium carbonate buffer (pH 9.0), and are applied to the derivatized glass surface from Example 2 at defined positions. For manual deposition, aliquots of 0.2 microliter each are applied with a pipetman. The array is incubated at room temperature in a moisture-saturated environment for at least two hours. The attachment reaction is terminated by immersing the glass surface in an aqueous 1% ammonia solution for five minutes with gentle agitation. The glass surface is then subjected to three 5-minute washes, using fresh portions of distilled water for each wash. The array is then soaked in 1 M phosphate buffered saline (PBS) solution for 2 hours at room temperature, then rinsed again for 5 minutes in distilled water.

15 Example 5: Surface Modification

The ammonia solution from Example 4 is replaced with a 1-5% aqueous solution of a different primary amine-containing molecule. A small amount (10%) of methanol or acetonitrile cosolvent is added, if necessary.

20 The glass surface is then subjected to three 5-minute washes, using fresh portions of distilled water for each wash. The surface is soaked in 1 M phosphate buffered saline (PBS) solution for 2 hours, then washed again for 5 minutes with distilled water. The glass surface is immersed in a dilute, aqueous solution of a protein-containing blocking solution for several minutes, then subjected to three 5-minute washes, using fresh portions of distilled water for each wash. Finally, the surface is air dried.

-20-

Example 6: Fusion Hybridization

5 50 microliters of a solution containing the RNA-protein fusions and consisting of 25 mM Tris-HCl (pH 8.0) and 100 mM potassium chloride are applied to the glass microchip surface in a chamber that can contain and seal
10 the liquid. The solution is maintained at a specific temperature (determined by the capture oligo design) for at least three hours. Excess, non-hybridized RNA-protein fusions are removed by washing with 25 mM Tris-HCl (pH 8.0) and 50 mM potassium chloride for several minutes at the incubation temperature. The protein chip is subjected to two 15-minute washes, using a
15 buffer that is more stringent and contains a lower salt concentration than the buffer used for the hybridization reaction.

Example 7: Generation of an Exemplary FLAG and HA11 Fusion Chip

Using the techniques essentially as described above, exemplary FLAG and HA11 fusion chips were generated as follows.

15 For silylation of the glass microchip surface, pre-cleaned 1 x 3 inch glass microscope slides (Goldseal, #3010) were treated with Nanostrip (Cyantek) for 15 minutes, 10% aqueous NaOH at 70°C for 3 minutes, and 1% aqueous HCl for 1 minute, thoroughly rinsing with deionized water after each solution. The slides were then dried in a vacuum desiccator over anhydrous
20 calcium sulfate for several hours. A 1% solution of aminopropyltrimethoxysilane (Gelest, Inc.) in 95% acetone / 5% water was prepared and allowed to hydrolyze for 20 minutes. The glass slides were immersed in the hydrolyzed silane solution for 5 minutes with gentle agitation. Excess silane was removed by subjecting the slides to ten 5-minute washes,
25 using fresh portions of 95% acetone / 5% water for each wash, with gentle agitation. The slides were then cured by heating at 110°C for 20 minutes.

-21-

To derivatize with a homobifunctional linker, the silane treated slides were immersed in a freshly prepared 0.2% solution of phenylene 1,4-diisothiocyanate (Aldrich Chemical Co.) in 90% DMF / 10% pyridine for two hours, with gentle agitation. The slides were washed sequentially with
5 90% DMF / 10% pyridine, methanol, and acetone. After air drying, the functionalized slides were stored at 0°C in a vacuum desiccator over anhydrous calcium sulfate.

Capture oligos were then designed and synthesized by standard techniques. In particular, the RNA employed to make the FLAG epitope fusion
10 (17 amino acids total) consisted of 5'-r(UAA UAC GAC UCA CUA UAG GGA CAA UUA CUA UUU ACA AUU ACA AUG GAC UAC AAG GAC GAU GAC GAU AAG GGC GGC UGG UCC CAC CCC CAG UUC GAG AAG) (SEQ ID NO: 1). The RNA employed to make the HA11 epitope fusion (20 amino acids total) consisted of 5'-r(UAA UAC GAC UCA CUA UAG GGA CAA UUA CUA UUU ACA AUU ACA AUG UAC CCC UAC GAC GUG CCC GAC UAC GCC GGC GGC UGG UCC CAC CCC CAG UUC GAG AAG) (SEQ ID NO: 2). In addition, in each case, the following DNA linker, which also contained the essential puromycin moiety at its 3'-end, was ligated to the 3'-terminus of the RNA message:
15 5'-d(AAAAAAAAAAAAAAAAAAAAAACC) (SEQ ID NO: 3).

Specific, non-interacting, and thermodynamically isoenergetic sequences along the target RNAs were identified to serve as capture points. The software program HybSimulator v2.2 (Advanced Gene Computing Technology, Inc.) facilitated the identification and analysis of potential capture
25 probes. A single specific capture probe for each RNA was ultimately identified (CPflag and CPha11). In addition, two sequences common to each RNA (CPt7, CPtag) were also identified to serve as positive controls. Four non-sense

-22-

sequences (CPau1, CPau5, CPirs, CPkt3) were generated as well to serve as negative controls. In total, eight unique sequences were selected. These oligonucleotides were prepared so that they could be attached to the chip surface at either the 3'- or 5'-terminus. Therefore, 16 capture probes were
5 prepared comprising eight unique sequences. The following is a list of these capture probe sequences (5' to 3') (SEQ ID NOS: 4-11):

	CPt7:	TGTAAATAGTAATTGTCCC
	CPtag:	CTTCTCGAACTGGG
	CPau1:	CCTGTAGGTGTCCAT
10	CPau5:	CAGGTAGAACGTCGGT
	CPflag:	CATCGTCCTTGTAGTC
	CPha11:	CGTCGTAGGGGTA
	CPirs:	CCGCTCCTGATGTA
	CPkt3:	TCGGGAGGCATTG.

15 Oligonucleotide capture probes were chemically synthesized in the 3' to 5' direction by coupling standard phosphoramidite monomers using an automated DNA synthesizer (PE BioSystems Expedite 8909). Typically, 500 angstrom controlled-pore glass supports were used at the 0.2 micromole scale. In the case of 5'-attachment, after the desired probe sequence had been
20 assembled (using A, G, C, and T monomers), four hexaethylene oxide phosphoramidite monomers (Glen Research) were added to the 5'-terminus. The coupling wait time was extended to 15 minutes by modifying the synthesizer program. Additional hexaethylene oxide monomer units were added in the same way. C-6 Amino phosphoramidite (Glen Research) was then
25 added to the 5' terminus; the coupling wait time was again extended to 15

-23-

minutes. The acetic anhydride capping step and the final acidic detritylation were eliminated. In the case of 3'-attachment, oligonucleotide synthesis began with a controlled-pore glass support bearing orthogonally protected primary hydroxyl and amino functionalities (Glen Research). Chain elongation began
5 on the hydroxyl group, and the amino group remained protected during oligomer assembly, only being unveiled during the final deprotection. The first four monomers to be added were hexaethylene oxide units, followed by the standard A, G, C, and T monomers. All capture oligo sequences were cleaved from the solid support and deprotected with ammonium hydroxide,
10 concentrated to dryness, precipitated in ethanol, and purified by reverse-phase HPLC using an acetonitrile gradient in triethylammonium acetate buffer. Appropriate fractions from the HPLC were collected, evaporated to dryness in a vacuum centrifuge, and then coevaporated with a portion of water.

To attach the purified, amine-labeled capture oligos, the oligos were
15 adjusted to a concentration of 250 micromolar in 50 mM sodium carbonate buffer (pH 9.0) containing 10% glycerol. The oligos were then robotically applied (MicroGrid, BioRobotics) to the derivatized glass surface described above at defined positions in a 5 x 5 x 16 array pattern (384 spots) within a 20 x 20mm area. The layout of these capture probes is shown schematically in
20 Figure 3. A 16-pin tool was used to transfer the liquid, producing 200 micron features with a pitch of 600 microns. Each sub-grid of 24 spots represented a single capture probe (i.e., 24 duplicate spots). The array was incubated at room temperature in a moisture-saturated environment for 12-18 hours. The attachment reaction was terminated by immersing the glass surface in an
25 aqueous 1% ammonia solution for five minutes with gentle agitation. The glass surface was then subjected to three 5-minute washes, using fresh portions of distilled water for each wash. The array was then soaked in a 10X PBS

-24-

(phosphate buffered saline) solution for 2 hours at room temperature, and then rinsed again for 5 minutes in distilled water.

RNA-protein fusions between the peptides containing the FLAG and HA11 epitopes and their corresponding mRNAs were produced as generally described by Szostak et al., WO 98/31700; and Roberts and Szostak, Proc. Natl. Acad. Sci. USA 94:12297-12302, 1997. The polymerase chain reaction using Taq polymerase (Promega) was used to amplify the sequences 5'-TAA TAC GAC TCA CTA TAG GGA CAA TTA CTA TTT ACA ATT ACA ATG GAC TAC AAG GAC GAT GAC GAT AAG GGC GGC TGG TCC CAC CCC CAG TTC GAG AAG (SEQ ID NO: 12) and 5'-TAA TAC GAC TCA CCC CAC GAC GTG CCC GAC TAC GCC GGC GGC TGG TCC CAC CCC CAG TTC GAG AAG (SEQ ID NO: 13) for FLAG and HA11, respectively, using the oligonucleotide primers 5'-TAA TAC GAC TCA CTA TAG GGA CAA TTA CTA TTT ACA ATT (SEQ ID NO: 14) and 5'-AGCGGATGCCTCTCGAACTGGGGTGGGA (SEQ ID NO: 15). The resulting PCR products were transcribed in vitro using T7 RNA polymerase (Ambion) to produce an mRNA containing the coding region for the FLAG and HA11 epitopes and the TMV untranslated region. This RNA was ligated to a DNA linker 5'-AAA AAA AAA AAA AAA AAA AAA AAA AAA CC (SEQ ID NO: 3) containing a 5' phosphate and a 3' puromycin by T4 DNA ligase (Promega) in the presence of an 80:20 mixture of the following two DNA splints: 5'-TGCAACGACCAACTTTTTTAGCGCATGC (SEQ ID NO: 16) and 5'-TGCAACGACCAACTTTTTNAGCGCATGC (SEQ ID NO: 17), each containing two biotin moieties at the 5' terminus. The resulting RNA-DNA chimera was purified by binding to Immobilized NeutrAvidin (Pierce), washing to remove unligated material, and eluting by displacement

-25-

using the sequence 5'-GCATCCGCTAAAAAAAAAGTTGGTCGTTGC (SEQ ID NO: 18). Subsequent translations were performed in rabbit reticulocyte lysate (Ambion) according to the manufacturer's instructions except that MgCl₂ (150 mM) and KCl (425 mM) were added after 30 minutes

5 to promote the formation of the puromycin-peptide bond. The RNA-peptide fusions were then purified by oligo dT affinity chromatography (Pharmacia), quantitated by scintillation counting of the incorporated vs. added ³⁵S methionine (Amersham), and concentrated to a low volume via membrane filtration (MicroCon).

10 For hybridization of the fusions to the immobilized capture probes, aliquots of each of the FLAG and HA11 fusions, corresponding to 1.0 picomole each, were combined and adjusted to 5X SSC (saline sodium citrate) + 0.02% Tween-20 in a volume of 20 microliters. The solution was applied to the glass chips described above, coverslips were placed on top, and the slides were

15 placed in a moisture-saturated chamber at room temperature. After 18 hours the coverslips were removed, and the slides were washed sequentially with stirred 500 mL portions of 1X SSC + 0.02% Tween-20, 1X SSC + 0.02% Tween-20, and 1X SSC for 5 minutes each, followed by a brief rinse with 0.2X SSC. After removal of liquid the slides were allowed to briefly air-dry.

20 To detect hybridization, the FLAG and HA11-fusion chip was exposed to a phosphorimage screen (Molecular Dynamics) for 60 hours by direct contact between the screen and the chip. This allowed identification of the areas that contained hybridized fusions, since the peptides contained a ³⁵S methionine radiolabel which was detectable by the phosphor storage screen.

25 As shown in Figure 4, analysis of the phosphorimage revealed that the fusions had successfully hybridized to their respective capture probes targeting specific areas of the RNA message (i.e., CPflag and CPha11). In addition, the four

-26-

non-sense capture probes, which were not complementary to any region of the FLAG or HA11 RNA, did not give any appreciable signal (i.e., CPau1, CPau5, CPirs, CPkt3). The positive control capture probe CPtag produced the expected signal, but the corresponding positive control capture probe CPt7 did 5 not, likely due to degradation (e.g., exonuclease contamination) of the 5'-region of the targeted RNA. These results demonstrated the feasibility of addressing a mixture of peptides (as fusions) to specific locations on the surface of a chip. Both the 3'-attached capture probes and the 5'-attached capture probes were effective.

10 A duplicate chip was probed with a monoclonal antibody that recognized the HA11 epitope. All of the following steps were performed at 4°C. Nonspecific sites were first blocked with a solution containing 1X PBS (phosphate buffered saline) + 1% BSA (bovine serum albumin, RNase free grade, Ambion) + 0.02% Tween-20 for 1 hour under a coverslip. The blocking 15 solution was removed and 50 microliters of HA.11 monoclonal antibody (100:1 dilution, Berkeley Antibody Co.) in 1X PBS + 0.02% Tween-20 was applied to the chip under a coverslip. After 2 hours the coverslip was removed, and the chip was washed with three 50mL portions of 1X PBS + 0.02% Tween-20 for 5 minutes each, with gentle agitation. Excess liquid was removed and then 50 20 microliters of Cy3-labeled goat anti-mouse IgG (400:1 dilution, Amersham Pharmacia Biotech) in 1X PBS + 0.02% Tween-20 was added under a coverslip. After 1 hour the coverslip was removed, and the chip was washed in three 50mL portions of 1X PBS + 0.02% Tween-20 for 5 minutes each, with gentle agitation. Excess liquid was removed, and the chip was allowed to 25 air-dry at room temperature. The chip was subsequently analyzed at 10 micron pixel resolution with a confocal laser scanner (ScanArray 3000, General Scanning) using preset excitation and emission wavelengths tuned to the Cy3

-27-

fluorophore. As shown in Figure 5, the resulting fluorimage was in accord with the phosphorimage and demonstrated that the HA11 peptide, which was covalently linked to its RNA message and fixed to the chip surface, was functional and was available to interact with its binding partner (the HA11 5 monoclonal antibody). Moreover, although both the FLAG-fusion and the HA11-fusion were presented on the chip surface, the HA11 monoclonal antibody was specific for its own epitope. In addition, the 3'-attachment capture probes generally provided a better signal than the 5'-attachment capture probes. Without being bound to a particular theory, this may reflect the greater 10 accessibility of the epitope when it is oriented away from the chip surface.

Example 8: Generation of an Exemplary Myc Fusion Chip

Using the techniques essentially as described above, an exemplary Myc fusion chip was also generated as follows.

For silylation of the glass surface, select grade, low-iron content, 15 pre-cleaned 25 x 75mm glass microscope slides (VWR Scientific, #48311-950) were used as supplied. A 1% solution of aminopropyltrimethoxysilane (Gelest, Inc.) in 95% acetone / 5% water was prepared and allowed to hydrolyze for 20 minutes. The glass slides were immersed in the hydrolyzed silane solution for 5 minutes with gentle agitation. Excess silane was removed by subjecting the 20 slides to ten 5-minute washes, using fresh portions of 95% acetone / 5% water for each wash, with gentle agitation. The slides were then cured by heating at 110°C for 20 minutes.

To derivatize with a homobifunctional linker, the silane treated slides 25 were immersed in a freshly prepared 0.2% solution of phenylene 1,4-diisothiocyanate (Aldrich Chemical Co.) in 90% DMF / 10% pyridine for two hours, with gentle agitation. The slides were washed sequentially with

-28-

90% DMF / 10% pyridine, methanol, and acetone. After air drying, the functionalized slides were stored at 0°C in a vacuum desiccator over anhydrous calcium sulfate.

The capture oligos were synthesized based on the Myc sequence. In 5 particular, the RNA employed to make the c-myc fusion (33 amino acids total) consisted of the following sequence:

5'-r(UAAUACGACUCACUAUAGGGACAAUUACAUUUACAAUUACA
AUGGGGACAAUUACUAUUACAAUUACAAUGCUGAAGAACAGA
AACUGAUCUCUGAAGAAGACCUGCUGCGUAAACGUCGUGAACAGC
10 UGAAACACAAACUGGAACAGCUGCGUAACUCUUGCGCU) (SEQ ID
NO: 19). In addition, the following DNA linker, which also contains the essential puromycin moiety, was ligated to the 3'-terminus of the RNA message: 5'-d(AAAAAAAAAAAAAAAAAAAAAAAAACC) (SEQ ID
NO: 3). Three non-overlapping and thermodynamically isoenergetic 20-mer
15 sequences along the RNA were identified to serve as capture points. In addition, dA25 (on the ligated DNA) was selected as a fourth target area. The targeted sequences began at nucleotide positions 1, 33, 80, and 125 (CP01,
CP33, CP80 and CP125, respectively). A mismatch sequence, derived from target sequence 33 and containing four internal and adjacent nucleotide
20 mismatches, was also designed (CPmm). A non-sense sequence, corresponding to the reverse-orientation of CP33, was also utilized as a negative control (CPns). The following is a list of the capture probe sequences that were employed (5' to 3') (SEQ ID NOS: 20-25):

25 CP01: TTGTAAATAGTAATTGTCCC
CP33: AGAGATCAGTTCTGTTCTT
CP80: AGTTTGTGTTTCAGCTGTT

-29-

CP125: TTTTTTTTTTTTTTTTTTTTTTT

Cpmm: AGAGATCTCAATCTGTTCTT

Cpns: TTCTTGTCCTTGACTAGAGA

Oligonucleotide capture probes were chemically synthesized in the 3'
5' to 5' direction by coupling standard phosphoramidite monomers with an
automated DNA synthesizer (PE BioSystems Expedite 8909). Typically, 500
angstrom controlled-pore glass supports were used at the 0.2 micromole scale.
After the desired probe sequence had been assembled (using A, G, C, and T
monomers), hexaethylene oxide phosphoramidite monomer (Glen Research)
10 was added to the 5'-terminus. The coupling wait time was extended to 15
minutes by modifying the synthesizer program. Additional hexaethylene oxide
monomer units were added in the same way. C-6 Amino phosphoramidite
(Glen Research) was then added to the 5' terminus; the coupling wait time was
again extended to 15 minutes. The acetic anhydride capping step and the final
15 acidic detritylation were eliminated. Capture oligo sequences were cleaved
from the solid support and deprotected with ammonium hydroxide,
concentrated to dryness, precipitated in ethanol, and purified by reverse-phase
HPLC using an acetonitrile gradient in triethylammonium acetate buffer.
Appropriate fractions from the HPLC were collected, evaporated to dryness in
20 a vacuum centrifuge, and then coevaporated with a portion of water.

To attach these purified, amine-labeled capture oligos, the oligos
were adjusted to a concentration of 500 micromolar in 100 mM sodium
carbonate buffer (pH 9.0) and were applied to the derivatized glass surface at
defined positions in a 6 x 6 array pattern (36 spots) within a 20 x 20mm area
25 (as shown in Figure 6). CP01 was applied to locations A1, B1, C1 and A4, B4,
C4. CP33 was applied to locations D1, E1, F1 and D4, E4, F4. CP80 was

-30-

applied to locations A2, B2, C2 and A5, B5, C5. CP125 was applied to locations D2, E2, F2 and D5, E5, F5. Cpmm was applied to locations A3, B3, C3 and A6, B6, C6. Cpns was applied to locations D3, E3, F3 and D6, E6, F6. For manual deposition, aliquots of 0.2 microliter each were applied with a

5 pipetman. The array was incubated at room temperature in a moisture-saturated environment for 12-18 hours. The attachment reaction was terminated by immersing the glass surface in an aqueous 1% ammonia solution for five minutes with gentle agitation. The glass surface was then subjected to three 5-minute washes, using fresh portions of distilled water for each wash.

10 The array was then soaked in a 10X PBS (phosphate buffered saline) solution for 2 hours at room temperature, and then rinsed again for 5 minutes in distilled water.

RNA-protein fusions between a 33 amino acid peptide containing the c-myc epitope and its mRNA were produced as described by Szostak et al.,

15 WO 98/31700; and Roberts and Szostak, Proc. Natl. Acad. Sci. USA 94:12297-12302, 1997. The polymerase chain reaction using Taq polymerase (Promega) was used to amplify the sequence 5'-AGC GCA AGA GTT ACG CAG CTG TTC CAG TTT GTG TTT CAG CTG TTC ACG ACG TTT ACG CAG CAG GTC TTC TTC AGA GAT CAG TTT CTG TTC TTC AGC CAT (SEQ ID NO: 26) using oligonucleotide primers 5'-AGC GCA AGA GTT ACG CAG CTG (SEQ ID NO: 27) and 5'-TAA TAC GAC TCA CTA TAG GGA CAA TTA CTA TTT ACA ATT ACA ATG GCT GAA GAA CAG AAA CT (SEQ ID NO: 28). The resulting PCR product was transcribed in vitro using T7 RNA polymerase (Ambion) to produce an mRNA containing the coding region for

20 the c-myc epitope and the TMV untranslated region. This RNA was ligated to a DNA linker 5'-AAA AAA AAA AAA AAA AAA AAA AAA CC (SEQ ID NO: 3) containing a 5' phosphate and a 3' puromycin by T4 DNA

25

-31-

ligase (Promega) in the presence of a DNA splint with the sequence TTT TTT TTT TAG CGC AAG A (SEQ ID NO: 29). The resulting 154mer RNA-DNA chimera was purified by denaturing polyacrylamide gel electrophoresis (6% acrylamide). Translation was performed in rabbit reticulocyte lysate (Ambion)

5 according to the manufacturer's instructions except that KCl (500 mM) was added after 30 minutes to promote the formation of the puromycin-peptide bond. The RNA-peptide fusion was purified by oligo dT affinity chromatography (Pharmacia), quantitated by scintillation counting of the incorporated vs. added 35 S methionine (Amersham), and dried to a pellet. 2.5

10 pmol of the c-myc fusion was produced.

To hybridize to the capture probes, the dry myc-fusion pellet was taken up with 20 microliters of 5X SSC (saline sodium citrate) + 0.02% SDS, mixed, and then briefly centrifuged. The solution was applied to the slide described above, a coverslip was placed on top, and the slide was placed in a

15 moisture-saturated chamber at room temperature. After 18 hours the coverslip was removed, and the slide was washed sequentially with stirred 500 mL portions of 5X SSC + 0.02% SDS, 2.5X SSC + 0.01% SSC, 2.5X SSC, and 1.25X SSC for 5 minutes each. After removal of liquid the slide was allowed to briefly air-dry.

20 To detect hybridization of the Myc fusions, the glass chip was exposed to a phosphorimage screen (Molecular Dynamics) for four hours by direct contact between the screen and the chip. This allowed identification of the areas that contained hybridized myc-fusion, since the myc peptide contained a 35 S methionine radiolabel which was detectable by the phosphor

25 storage screen. As shown in Figure 7, analysis of the phosphorimage revealed that the myc-fusion had successfully hybridized to each of the four capture probes that targeted the myc RNA message and DNA linker sequence. In

-32-

addition, the non-sense capture probe, which was not complementary to any region of the myc RNA, did not give any appreciable signal. The capture probe sequence that contained several mismatches produced only a small amount of signal. These results demonstrated that it was possible to address a peptide (as
5 a fusion) to a specific location on the surface of a chip.

After phosphorimage analysis, the same chip was probed with a monoclonal antibody that recognized the c-myc epitope. All of the following steps were performed at 4°C. Nonspecific sites were first blocked with a solution containing 1X PBS (phosphate buffered saline) + 1% BSA (bovine
10 serum albumin, Sigma Chemical Co.) + 0.1 unit per microliter RNase inhibitor (Ambion) for 1 hour under a coverslip. The blocking solution was removed, and 50 microliters of 9E10 monoclonal antibody in 1X PBS (400:1 dilution, Berkeley Antibody Co.) was applied to the chip under a coverslip. After 1 hour the coverslip was removed, and the chip was washed with three 50mL portions
15 of 1X PBS for 5 minutes each, with gentle agitation. Excess liquid was removed, and then 50 microliters of Cy3-labeled goat anti-mouse IgG in 1X PBS (400:1 dilution, Amersham Pharmacia Biotech) was added under a coverslip. After 1 hour the coverslip was removed, and the chip was washed in three 50mL portions of 1X PBS for 5 minutes each, with gentle agitation.
20 Excess liquid was removed, and the chip was allowed to air-dry at room temperature. The chip was subsequently analyzed at 10 micron pixel resolution with a confocal laser scanner (ScanArray 3000, General Scanning) using preset excitation and emission wavelengths tuned to the Cy3 fluorophore. As shown in Figure 8, the resulting fluorimage was in accord with the phosphorimage and
25 demonstrated that the myc peptide, which was covalently linked to its RNA message and fixed to the chip surface, was functional and was available to interact with its binding partner (the monoclonal antibody).

All publications and patents mentioned in this specification are herein incorporated by reference to the same extent as if each individual publication or patent was specifically and individually indicated to be incorporated by reference.

5

Other Embodiments

From the foregoing description, it will be apparent that variations and modifications may be made to the invention described herein to adopt it to various usages and conditions. Such embodiments are also within the scope of the following claims.

10

What is claimed is:

-34-

Claims

1. A solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound.
2. A solid support comprising an array of immobilized capture probes, wherein each of said capture probes is attached to the surface of said solid support through a non-nucleosidic spacer group, and wherein each of said capture probes comprises an oligonucleotide sequence to which a nucleic acid-protein fusion is bound.
3. A solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a ribosome display particle is bound.
4. The solid support of claim 1, 2, or 3, wherein said nucleic acid-protein fusion is an RNA-protein fusion.
5. The solid support of claim 1, 2, or 3, wherein said capture probe is bound to said nucleic acid-protein fusion by base pairing.
6. The solid support of claim 1, 2, or 3, wherein said protein is encoded by said nucleic acid.
- 20 7. The solid support of claim 1, 2, or 3, wherein said spacer group

-35-

comprises a polyalkylene oxide, polyethylene oxide, or hexaethylene oxide.

8. The solid support of claim 1, 2, or 3, wherein said capture probe comprises a photocleavable linker.

9. The solid support of claim 1, 2, or 3, wherein said oligonucleotide sequence comprises a modified base, an internucleotide analog, or a carbohydrate modification.

10. The solid support of claim 9, wherein said modified base is 5-propyne pyrimidine, said internucleotide analog is a 3'-phosphoramidate linkage, or said carbohydrate modification is a 2'-O-methyl group.

11. The solid support of claim 1, 2, or 3, wherein said nucleic acid-protein fusion comprises a hybridization tag sequence.

12. The solid support of claim 11, wherein said hybridization tag sequence comprises a modified base, an internucleotide analog, or a carbohydrate modification.

13. The solid support of claim 1, 2, or 3, wherein said capture probe further comprises a reactive moiety.

14. The solid support of claim 13, wherein said reactive moiety is a primary amino group.

15. The solid support of claim 1, 2, or 3, wherein said solid support

-36-

is a glass or silica-based chip.

16. The solid support of claim 1, 2, or 3, wherein said nucleic acid-protein fusion is covalently linked to said capture probe.

17. The solid support of claim 16, wherein said capture probe
5 comprises one or more psoralen moieties.

18. A method for preparing a solid support, said method comprising the steps of:

- (a) preparing a capture probe by linking a spacer group to an oligonucleotide sequence;
- 10 (b) attaching said capture probe to said solid support; and
- (c) binding a nucleic acid-protein fusion to said capture probe.

19. A method for preparing a solid support, said method comprising the steps of:

- (a) attaching a spacer group to a surface of said solid support;
- 15 (b) attaching a bifunctional linker to said spacer group;
- (c) attaching a capture probe to said bifunctional linker; and
- (d) binding a nucleic acid-protein fusion to said capture probe.

20. The method of claim 18 or 19, wherein said nucleic acid-protein fusion is an RNA-protein fusion.

20 21. A method for detecting an interaction between a protein and a compound, said method comprising the steps of:

-37-

(a) providing a solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound;

5 (b) contacting said solid support with a candidate compound under conditions which allow an interaction between the protein portion of said nucleic acid-protein fusion and said compound; and

(c) analyzing said solid support for the presence of said compound as an indication of an interaction between said protein and said compound.

10 22. A method for detecting an interaction between a protein and a compound, said method comprising the steps of:

(a) providing a population of nucleic acid-protein fusions;

(b) contacting said population of nucleic acid-protein fusions with a candidate compound under conditions which allow an interaction between the 15 protein portion of said nucleic acid-protein fusion and said compound;

(c) contacting the product of step (b) with a solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion binds; and

20 (d) analyzing said solid support for the presence of said compound as an indication of an interaction between said protein and said compound.

23. The method of claim 21 or 22, wherein said nucleic acid-protein fusion is an RNA-protein fusion.

24. The method of claim 21 or 22, wherein said compound is

labeled.

25. The method of claim 21 or 22, wherein said compound is a protein, a therapeutic, an enzyme, or a nucleic acid.

26. An array of nucleic acid-protein fusions, said array comprising
5 at least 10^2 different fusions/cm².

27. The array of claim 26, wherein said array comprises at least 10^4 different fusions/cm².

28. The array of claim 26, wherein said nucleic acid-protein fusions are RNA-protein fusions.

10 29. A method for generating an addressable array of molecules, said method comprising:

(a) providing a solid support on which an array of nucleic acid molecules is immobilized;

15 (b) contacting said solid support with a population of addressable molecules; and

(c) allowing said addressable molecules to orient themselves on said solid support by sequence-dependent recognition and binding of said immobilized nucleic acid molecules.

30. The method of claim 29, wherein said addressable array of
20 molecules is an array of nucleic acid-protein fusions.

-39-

31. The method of claim 30, wherein said nucleic acid-protein fusions are RNA-protein fusions.

32. The method of claim 29, wherein said sequence-dependent recognition and binding comprises base pairing.

5 33. The method of claim 29, wherein said solid support is a glass or silica-based chip.

10 34. The method of claim 29, wherein said nucleic acid molecules immobilized on said solid support are capture probes, each comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which said addressable molecule binds.

(54) Title: ADDRESSABLE PROTEIN ARRAYS

(57) Abstract

Disclosed herein are arrays of nucleic acid-protein fusions which are immobilized to a solid surface through capture probes which include a non-nucleosidic spacer group and an oligonucleotide sequence to which the fusion (such as an RNA-protein fusion) is bound. Also disclosed herein are solid supports on which these arrays are immobilized as well as methods for their preparation and use (for example, for screening for protein-compound interactions such as protein-therapeutic compound interactions).

ADDRESSABLE PROTEIN ARRAYS

Background of the Invention

5 The invention relates to fixed arrays of nucleic acid-protein fusions and, in particular, RNA-protein fusions, on solid supports.

Certain macromolecules, such as proteins, are known to interact specifically with other molecules based on the three-dimensional shapes and electronic distributions of those molecules. For example, proteins interact
10 selectively with other proteins, with nucleic acids, and with small-molecules. Modern pharmaceutical research relies on the study of these interactions; the development of new drugs depends on the discovery of compounds that bind specifically to biologically important molecules.

15 The discovery of a single drug candidate can require the screening of thousands of compounds. It is therefore important to be able to screen large numbers of compounds rapidly and efficiently. One method for screening a large number of compounds is to fix possible binding partners, such as proteins, to a solid support.

It is difficult to prepare arrays of isolated proteins on solid supports,
20 however, for a variety of reasons. First of all, proteins cannot always be easily attached to the planar surfaces traditionally used to make other fixed arrays, such as nucleic acid microchips. More importantly, because proteins can interact with the functional groups on the surfaces of these supports, the proximity of the protein to the surface can lead to disruption of the protein
25 structure.

Summary of the Invention

In general, the invention features a solid support including an array of immobilized capture probes; each of the capture probes includes a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound (for example, hybridized or covalently bound). In preferred embodiments, the nucleic acid-protein fusion is an RNA-protein fusion, and the protein component is encoded by the nucleic acid (for example, the RNA). The spacer group can include a polyalkylene oxide, for example, polyethylene oxide. A preferred spacer group includes hexaethylene oxide.

10 The capture probe may also include a photocleavable linker.
The oligonucleotide sequence can include a modified base, such as 5-propyne pyrimidine. It can also include an internucleotide analog (such as 3'-phosphoramidate) or a carbohydrate modification (such as a 2'-O-methyl group). The nucleic acid-protein fusion can include a hybridization tag

15 sequence. The hybridization tag sequence can also include a modified base, an internucleotide analog, or a carbohydrate modification.

In a preferred embodiment, the capture probe further includes a reactive moiety (for example, a nucleophilic group), such as a primary amino group. In another preferred embodiment, the nucleic acid-protein fusion is

20 covalently linked to the capture probe (for example, by photo-crosslinking); in one preferred approach, this is accomplished by including one or more psoralen moieties in the capture probe or in the capture probe-fusion hybridization reaction mixture. A preferred solid support is a glass or silica-based chip.

In a related aspect, the invention features a solid support including an array of immobilized capture probes; each of the capture probes is attached to the surface of the solid support through a non-nucleosidic spacer group, and

-3-

each of the capture probes includes an oligonucleotide sequence to which a nucleic acid-protein fusion (for example, an RNA-protein fusion) is bound (for example, hybridized or covalently bound).

In another related aspect, the invention features a solid support
5 including an array of immobilized capture probes; each of the capture probes includes a non-nucleosidic spacer group and an oligonucleotide sequence to which a ribosome display particle is bound (for example, hybridized or covalently bound).

In yet another related aspect, the invention features a method for
10 preparing a solid support. The method includes the steps of: (a) preparing a capture probe by linking a spacer group to an oligonucleotide sequence; (b) attaching the capture probe to the solid support; and (c) binding (for example, hybridizing or covalently binding) a nucleic acid-protein fusion (for example, an RNA-protein fusion) to the capture probe.

15 The invention also features a second general method for preparing a solid support. This method includes the steps of: (a) attaching a spacer group to a surface of the solid support; (b) attaching a bifunctional linker to the spacer group; (c) attaching a capture probe to the bifunctional linker; and (d) binding (for example, hybridizing or covalently binding) a nucleic acid-protein fusion
20 (for example, an RNA-protein fusion) to the capture probe.

In a second aspect, the invention features a method for detecting an interaction between a protein and a compound. The method includes the steps of: (a) providing a solid support including an array of immobilized capture probes, where each of the capture probes includes a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound (for example, hybridized or covalently bound); (b) contacting the solid support with a candidate compound under conditions which allow an

interaction between the protein portion of the nucleic acid-protein fusion and the compound; and (c) analyzing the solid support for the presence of the compound as an indication of an interaction between the protein and the compound.

5 Alternatively, the invention features another method for detecting an interaction between a protein and a compound; this method involves the steps of: (a) providing a population of nucleic acid-protein fusions; (b) contacting the population of nucleic acid-protein fusions with a candidate compound under conditions which allow an interaction between the protein portion of the
10 nucleic acid-protein fusion and the compound; (c) contacting the product of step (b) with a solid support that includes an array of immobilized capture probes, each of the capture probes including a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion binds (for example, hybridizes or covalently binds); and (d) analyzing the solid
15 support for the presence of the compound as an indication of an interaction between the protein and the compound.

In a preferred embodiment of each of the above methods, the nucleic acid-protein fusion is an RNA-protein fusion. In another preferred embodiment, the compound is labeled. Compounds that can be screened using
20 these methods include, without limitation, proteins, drugs, therapeutics, enzymes, and nucleic acids.

In a third aspect, the invention features an array (for example, an addressable array) of nucleic acid-protein fusions including at least 10^2 different fusions/cm². Preferably, the nucleic acid-protein fusions are RNA-protein fusions, and the array includes at least 10^4 different fusions/cm².

In a related aspect, the invention features a method for generating an addressable array of molecules. The method involves: (a) providing a solid

-5-

support on which an array of nucleic acid molecules is immobilized; (b) contacting the solid support with a population of addressable molecules; and (c) allowing the addressable molecules to orient themselves on the solid support by sequence-dependent recognition and binding of the immobilized nucleic acid
5 molecules.

In preferred embodiments of this method, the addressable array of molecules is an array of nucleic acid-protein fusions (for example, an array of RNA-protein fusions); the addressable molecules orient themselves on the solid support by base pairing (for example, hybridization) with the immobilized
10 nucleic acid molecules; the solid support is a glass or silica-based chip; and the nucleic acid molecules immobilized on the solid support are capture probes, each including a non-nucleosidic spacer group and an oligonucleotide sequence to which the addressable molecule binds.

As used herein, by an "array" is meant a fixed pattern of
15 immobilized objects on a solid surface or membrane. Typically, the array is made up of nucleic acid-protein fusion molecules (for example, RNA-protein fusion molecules) bound to capture nucleic acid sequences which themselves are immobilized on the solid surface or membrane. The array preferably includes at least 10^2 , more preferably at least 10^3 , and most preferably at least
20 10^4 different fusions, and these fusions are preferably arrayed on a 125 x 80 mm, and more preferably on a 10 x 10 mm, surface. By an "addressable array" is meant that the locations, or addresses, on the solid support of the members of the array (for example, the nucleic acid-protein fusions) are known; the members of the array are referred to as "addressable molecules" and are
25 utilized in methods for screening for subsequent molecular interactions (for example, for screening for interactions between the addressable nucleic acid-protein fusions and candidate therapeutics).

-6-

By "nucleic acid-protein fusion" is meant a nucleic acid covalently bound to a protein. By "nucleic acid" is meant any two or more covalently bonded nucleotides or nucleotide analogs or derivatives. As used herein, this term includes, without limitation, DNA, RNA, and PNA. By "protein" is 5 meant any two or more amino acids, or amino acid analogs or derivatives, joined by peptide or peptoid bond(s), regardless of length or post-translational modification. As used herein, this term includes, without limitation, proteins, peptides, and polypeptides.

By "hybridization tag" is meant a non-coding oligonucleotide 10 sequence that differs sufficiently in sequence from other nucleic acid sequences in a given population or reaction mixture that significant cross-hybridization does not occur. When multiple hybridization tags are utilized in a single reaction mixture, these tags also preferably differ in sequence from one another such that each has a unique binding partner under the conditions employed.

15 By a "population" is meant more than one molecule.

By a "solid support" is meant any solid surface including, without limitation, any chip (for example, silica-based, glass, or gold chip), glass slide, membrane, bead, solid particle (for example, agarose, sepharose, or magnetic bead), column (or column material), test tube, or microtiter dish.

20 Brief Description of the Drawings

Figure 1 is a drawing showing the silylation of a glass surface, the derivatization of the resulting amino groups, and the attachment of a capture probe to the modified surface.

25 Figure 2 is a drawing illustrating a capture probe containing a non-nucleosidic spacer group and a reactive moiety.

Figure 3 is a schematic diagram of the layout of the FLAG and

-7-

HA11 fusion chip capture probes utilized in Figures 4 and 5. In this Figure, t7, tag, au1, au5, flag, ha1, irs, and kt3 represent the capture probes CPt7 (positive control), CPtag (positive control), CPau1 (negative control), CPau5 (negative control), CPflag, CPha11, CPirs (negative control), and CPkt3 (negative control), respectively.

5 Figure 4 is a phosphorimage demonstrating hybridization of nucleic acid-protein fusions (FLAG and HA11) to capture probes immobilized on a chip.

Figure 5 is a fluorimage demonstrating hybridization of nucleic acid-10 protein fusions (FLAG and HA11) to capture probes immobilized on a chip and subsequent recognition with anti-HA11 monoclonal antibodies.

Figure 6 is a schematic diagram of the layout of the Myc fusion chip capture probes utilized in Figures 7 and 8. In this Figure, capture probes CP01, CP33, CP80, CP125, CPmm, and CPns (described herein) were arranged on the 15 chip as follows: CP01 at locations A1, B1, C1, A4, B4, and C4; CP33 at locations D1, E1, F1, D4, E4, and F4; CP80 at locations A2, B2, C2, A5, B5, and C5; CP125 at locations D2, E2, F2, D5, E5, and F5; CPmm at locations A3, B3, C3, A6, B6, and C6; and CPns at locations D3, E3, F3, D6, E6, and F6.

Figure 7 is a phosphorimage demonstrating hybridization of nucleic acid-protein fusions (Myc) to capture probes immobilized on a chip.

Figure 8 is a fluorimage demonstrating hybridization of nucleic acid-protein fusions (Myc) to capture probes immobilized on a chip and subsequent 20 recognition with anti-Myc monoclonal antibodies.

Description of the Preferred Embodiments

25 The invention features support-based, addressable arrays of proteins, and methods for preparing and using these arrays. The arrays are prepared by

-8-

fixing oligonucleotide sequences, the capture probes (or capture oligos), to a support in a defined array. The capture probes are then used to bind nucleic acid-protein fusions, such as RNA-protein fusions. Such binding may occur through base pairing (for example, through Watson-Crick base pairing, pseudo
5 Watson-Crick base pairing involving modified bases, or Hoogsteen base pairing) between the nucleic acid component of the fusion and a complementary capture probe, or may occur through any other type of sequence-dependent recognition and binding of the capture probe (including, without limitation, polyamide-mediated nucleic acid groove binding or specific
10 binding by nucleic acid-binding proteins such as transcription factors). The result of the binding interactions between the fusions and the capture probes is a defined, addressable array of proteins attached to a solid support.

A variety of materials can be used as the solid support. Examples of such materials include polymers (e.g., plastics), aminated surfaces, gold coated
15 surfaces, nylon membranes, polyacrylamide pads deposited on solid surfaces, silicon, silicon-glass (e.g., microchips), silicon wafers, and glass (e.g., microscope slides). Microchips, and particularly glass microchips, represent a preferred solid support surface.

If the surface is not already aminated, it can be modified to provide a
20 layer of amino groups. For example, a glass microscope slide can be treated with a silylating agent such as trialkoxyaminosilane to provide a surface of primary amino groups that exists as a monolayer or 3-8 molecular layers. This reaction is illustrated in Figure 1. The silane-treated surface is then derivatized with a homobifunctional or heterobifunctional linker that permits the
25 attachment of oligonucleotides at discrete positions. Phenylene 1,4-diisothiocyanate is a useful homobifunctional linker; amino-surfaces derivatized with this reagent have isothiocyanate functionalities that are

-9-

available to covalently react with the primary amino groups on the termini of oligonucleotides to form stable thiourea bonds, as shown in Figure 1.

The capture probes, i.e., the oligonucleotide sequences that are to be attached to the surface, are selected from the reverse-complements of the 5 nucleic acid components of the nucleic acid-protein fusions (the targets). Capture probes preferably have between 5 and 30 nucleotide units, and more preferably have about 20 nucleotide units. Considerations for the selection of the exact sequence for a particular capture probe include melting temperature (T_m), interference from competing target sequences, and potential secondary 10 structure in the target sequence. Ideally, each unique capture probe has the same T_m, i.e., they are isoenergetic, so a single hybridization and washing temperature can be used successfully for all capture-target pairs. Commercially available computer programs (e.g., Oligo 4.0) can be used to help identify sets 15 of capture probes with similar thermodynamic properties based on nearest neighbor treatments.

The capture probes are modified before they are attached to the surface. One or more non-nucleosidic spacers, such as polyethylene oxide, are added to the terminus of the oligo. Preferably, 1-20 spacers and, most preferably, 4 spacers are utilized. These spacers may be added to either the 5' 20 or preferably the 3' end of the oligonucleotide. A nucleophilic moiety is then attached to the spacer group. The result is a derivatized capture probe, as shown in Figure 2. A preferred spacer monomer includes hexaethylene oxide.

Non-nucleosidic spacers are preferred over nucleosidic spacers, such as poly-T, because non-nucleosidic spacers have greater flexibility. In 25 addition, their physical properties can be tailored relatively easily, and it is possible to minimize specific and non-specific nucleic acid interactions.

The spacers provide physical separation between the oligonucleotide

-10-

and the solid surface and prevent interaction of the proteins with the support surface. This separation is important to ensure effective hybridization between the support-bound capture probe and the nucleic acid-protein fusion. In addition, the separation helps to minimize denaturation of the protein; the 5 proteins are therefore able to adopt their native folded structures and remain functional.

Alternatively, the spacer groups can be attached directly to the solid support surface, instead of to the capture probes. For example, the spacer group can be attached to the amino groups on the surface. The bifunctional 10 linker can then be attached to the other end of the spacer group.

In addition to spacer groups, the capture probes may contain modifications that improve their hybridization properties and mismatch discrimination. For example, they may contain base analogs, such as 5-propyne pyrimidines, internucleotide analogues such as peptide nucleic acids 15 (PNA), in which the bases are connected by peptide-like linkages, or carbohydrate modifications.

The capture probes are suspended in an aqueous alkaline solution, then applied to defined positions of the support surface; the nucleophilic moieties at the termini of the capture probes react with the active sites of the 20 bifunctional linkers to form covalent bonds. The density of the capture probes can be controlled by adjusting reaction time and oligo concentration.

Alternatively, the density can be controlled by doping the solution with capture oligos that lack nucleophilic moieties or doping with simple organic compounds that possess amine functional groups.

25 The capture probes can be applied using liquid deposition techniques, such as inkjet delivery, robotic quill delivery or spotting, and other similar deposition methods. They can also be applied using manual methods,

-11-

such as pipetting. The feature sizes of the capture probes can range from one square micron (e.g., when robotic techniques are used) to one square millimeter (e.g., when a 0.2 microliter pipette is used). The result of the application of the capture probes is a defined, regular array of nucleic acid sequences.

5

After a sufficient reaction time, the excess capture probe is washed away, and the remaining unreacted isothiocyanate groups are blocked off. Dilute ammonia can be used as the blocking agent, resulting in a surface of phenyl thiourea groups. Blocking agents can also be selected to modify the 10 surface energy, i.e., the hydrophobicity of the solid support surface. The hydrophobicity of the solid support surface is important because it affects the background signal level and the extent of unwanted interaction of the protein portion of a nucleic acid-protein fusion with the surface. Examples of blocking agents that modify hydrophobicity are methylamine, amino alcohols, and 15 suitable amino-containing polyethylene oxide moieties.

15

Non-covalent blocking agents can also be used to further minimize non-specific interactions between the fusion and the solid support (e.g., glass) surface. Examples of such blocking agents include non-specific proteins such as BSA or casein, or similar commercially available blocking reagent 20 formulations marketed for use with membranes.

20

The capture probes arrayed on the surface of the solid support are then bound (for example, by hybridization) to nucleic acid-protein fusions, such as RNA-protein fusions. A solution containing the mixture of fusions is adjusted to an appropriate salt concentration, applied to the surface, and 25 incubated at a suitable temperature to allow for efficient binding (for example, hybridization) between the capture probe and the target sequence. The solution may also contain surfactants such as TWEEN-20, TRITON X-100, or SDS

-12-

(Sigma Chemical Co.) at concentrations of about 0.02% to about 1.0%; it may also include non-specific proteins, such as BSA.

The experimental variables of salt concentration, temperature, and hybridization time are a function of the capture oligo design. A preferred range 5 for the salt concentration is 25 mM to 2 M, with a concentration of about 750 mM being especially preferred. A preferred temperature range is from 5°C to 70°C, with 30°C being especially preferred. Preferred reaction times can be from 1 to 24 hours, with 3 hours being especially preferred. The variables for each experiment are determined empirically by standard methods. The 10 hybridization step can be performed in a simple chamber device that constrains the liquid sample and prevents evaporation.

When RNA-protein fusions are utilized as addressable arrays, the solution may also contain one or more components to suppress nuclease degradation of the RNA moiety. Preferred additions include (a) metal chelators 15 (e.g., EDTA or EGTA) at concentrations of between 1 - 10 mM, (b) placental RNase inhibitor protein (Promega) at concentrations of between 0.1 - 1 Unit/μl; and (c) Anti-RNase protein (Ambion) at concentrations of between 0.1 - 1 Unit/μl. A separate strategy to specifically suppress 5'-exonuclease degradation involves capping the 5'-terminus of the fusion RNA with a binding 20 molecule. The capping strategy may be used in conjunction with one or more of the components listed above. In one particular capping approach, a native or analog (e.g., PNA) nucleic acid sequence complementary to the 5'-terminus of the fusion RNA is added to generate a stable duplex at the 5'-end. The complementary sequence is preferably between 10 - 50 bases in length, and 25 most preferably about 20 bases in length. This added nucleic acid sequence may also contain pendant groove-binding, intercalating, or cross-linking moieties. Alternatively, native or analog nucleic acid sequences may be added

-13-

that form stable intermolecular hairpin, tetraloop, or pseudoknot secondary structures with the 5'-terminus of the RNA. In the latter case, these nucleic acids are preferably about 20 - 100 bases in length, with about 35 bases being especially preferred.

5 To the extent possible, the mixture of nucleic acid-protein fusions should be free of un-fused nucleic acids. Un-fused nucleic acids that are complementary to the capture probes will compete with the fusions for binding and will limit the amount of a given protein that can be displayed on the solid support. Preferably, at least 1% of the nucleic acid (for example, the RNA
10 message) is fused to protein.

Unique non-coding regions can be incorporated into the nucleic acid component of the fusion for the specific purpose of being "captured" by the capture probe; these non-coding regions are referred to as "hybridization tag sequences." The hybridization tag sequences may include the same analogue
15 units as are described above for the capture probes. In some cases, both the capture probe and the tag sequences can be modified so they hybridize preferentially with each other, thereby minimizing interference from the coding fusion sequences.

Upon completion of the binding step, unbound nucleic acid-protein
20 fusion is washed away with a buffer that has a higher stringency and a lower salt concentration than that used for the hybridization step. Again, the optimal buffer composition is determined empirically by standard methods. What remains upon completion of washing is an addressable array of proteins on the solid surface, attached via sequence-dependent recognition between the nucleic
25 acid component of the fusion and the surface-bound capture oligo. The position of each protein is defined, because each fusion corresponds to the complementary capture probe.

-14-

In addition, if desired, the nucleic acid component of the fusion may be covalently linked to a part of the solid support, the linker, or the capture probe. Such covalently linked fusions provide particularly robust and versatile addressable arrays that may be used, for example, in the screening methods 5 described herein. Covalently linked fusion arrays may be generated by any standard approach. According to one general technique, the fusions are addressed to specific locations on a solid surface via hybridization with corresponding capture probes, and a chemical cross-linking or attachment reaction is triggered to fix the location of the fusions on the solid support. One 10 method to achieve such a covalent link involves functionalizing the DNA capture oligos during chemical synthesis with one or more pendant psoralen moieties, preferably positioned near adenosine bases. After hybridizing the nucleic acid-protein fusion (for example, the RNA-protein fusion) to the support-bound capture oligos, the surface is exposed to long-wavelength UV 15 light (for example, at 350 nm). Light of this wavelength triggers a photoreaction between psoralen and an adjacent thymidine or uridine base in the duplex region, forming a cyclobutane linkage and permanently attaching the fusion to the solid support. Alternatively, psoralen itself (i.e., not linked to a capture probe) may be included in the hybridization solution or in a 20 subsequent separate solution. The psoralen molecule intercalates between bases in double-stranded regions. Upon irradiation with long-wavelength UV light, the intercalated psoralen cross-links with thymidine or uridine bases (intrastrand and interstrand) in a bifunctional mode, forming covalent links between the capture probe and the nucleic acid component of the fusion. Other 25 reactive, cross-linking reagents may also be used in place of psoralen in combination with triggering conditions appropriate for those reagents.

Ordered, addressable arrays of peptide fragments can also be

-15-

prepared. To prepare these arrays, the fusion library is generated from short synthetic DNA sequences or fragments of cDNAs or genomic DNAs. In another variation, ribosome display particles, such as those described in Gold et al., WO 93/03172, can be hybridized to the solid support to generate the protein array. Again, these particles are immobilized on the solid support through a hybridization reaction between the capture oligo and the protein-coding RNA.

Use

The addressable protein arrays of the present invention have many uses. For example, a library of proteins can be displayed on a support, such as 10 a microchip. This microchip can then be used to identify previously unknown protein-protein interactions. A probe protein can be detectably labeled, for example, with a radioisotope, chromophore, fluorophore, or chemiluminescent species, then incubated with the microchip. After the excess probe protein is washed away, the chip surface is analyzed for signal from the label. Detection 15 of a signal indicates interaction of the labeled protein with one or more unique members of the protein library. The identity of proteins that are able to bind to the probe protein can then be determined from the location of the spots on the chip that become labeled due to binding of the probe. The same approach can also be used to screen protein libraries for protein-ligand interactions and 20 protein-nucleic acid interactions.

Other methods can be used to detect protein-protein, protein-ligand, or protein-nucleic acid interactions. For example, when the solid surface used to form the protein array is a gold layer, surface plasmon resonance (SPR) can be used to detect mass changes at the surface. When gold surfaces are 25 employed, the reactive moiety on the oligonucleotide capture probe is a thiol group (rather than an amino group) and the gold surface need not be

-16-

functionalized to achieve capture probe attachment. Mass spectrometry (especially, Maldi-Tof) can also be used to analyze species bound to unique members of the protein library.

Another application of protein arrays is the rapid determination of 5 proteins that are chemically modified through the action of modifying enzymes such as protein kinases, acyl transferases, and methyl transferases. By incubating the protein array with the enzyme of interest and a radioactively labeled substrate, followed by washing and autoradiography, the location and hence the identity of those proteins that are substrates for the modifying 10 enzyme may be readily determined. Further localization of the modification sites can be achieved using ordered displays of fragments of these proteins.

The protein arrays can also be used to identify the unknown protein targets of therapeutically active compounds. For example, a therapeutic compound may be applied to a protein array derived from cellular RNA. 15 Detection of the captured therapeutic compound, either through its bound label or directly (for example, by mass spectrometry or surface plasmon resonance) reveals the compound's binding partner or partners. In addition, arrays can also be used in the development of protein-based diagnostics. For example, a solid support containing a variety of proteins associated with various illnesses can be 20 prepared. A single patient sample, which might contain one or more proteins whose interactions with the support-bound proteins would be indicative of certain illnesses, can then be contacted with the support. Thus, a single sample can be used to simultaneously detect the presence of several conditions, or to distinguish between conditions. Alternatively, addressable arrays may be used 25 to quantify target molecules in a sample. In one particular example, addressable arrays of single chain antibodies or antibody mimics may be used for quantifying a target protein (or proteins) in a biological sample. The arrays

-17-

can also be used in the emerging fields of proteomics and functional genomics.

The specific fusions that are identified as binding specifically to a probe molecule can be removed from the support surface. In one method, the fusion is released by disrupting hybridization with the capture probe. In one
5 particular approach, the specified fusion is physically separated from the rest of the fusions, then treated with a denaturing agent, such as a chemical reagent or heat, to disrupt the base pairing with the capture oligo. The liberated fusion is then recovered from the solution.

Alternatively, the entire capture probe can be detached. During solid
10 support preparation, a light-sensitive linker can be used to attach the capture probe to the solid surface. Following identification of the active fusion, a laser beam of the appropriate wavelength can be used to cleave the linker, thus releasing the desired fusion. Following release from the surface by any of the above methods, the fusion can be specifically recovered and manipulated, for
15 example, using PCR, and further characterized.

There now follow particular examples of the preparation of protein arrays according to the invention. These examples are provided for the purpose of illustrating the invention, and should not be construed as limiting.

Example 1: Silylation of a Glass Surface

20 Select grade, low-iron content, pre-cleaned 1 x 3 inch glass microscope slides (VWR Scientific) are prepared by heating with 1 M hydrochloric or nitric acid for 30 minutes at 70°C. The slides are then subjected to three 5-minutes washes, using fresh distilled water for each wash. A 1% solution of aminopropyltrimethoxysilane (Gelest, Inc.) in 95%
25 acetone/5% water is prepared and allowed to hydrolyze for at least five minutes. The glass slides are immersed in the hydrolyzed silane solution for

-18-

2-20 minutes with gentle agitation. Excess silane is removed by subjecting the slides to ten 5-minute washes, using fresh portions of 95% acetone/5% water for each wash, using gentle agitation. The slides are then cured by heating at 110°C for 20-45 minutes.

5 Example 2: Derivatization with a Homobifunctional Linker

Silane treated slides from Example 1 are immersed in a freshly prepared 0.2% solution of phenylene 1,4-diisothiocyanate (Aldrich Chemical Co.) in 90% DMF/10% pyridine for two hours, with gentle agitation. The slides are washed sequentially with 90% DMF/10% pyridine, methanol, and acetone. After air drying, the functionalized slides are stored at 0°C in a vacuum desiccator over anhydrous calcium sulfate.

Example 3: Synthesis of Capture Probes

Oligonucleotides are chemically synthesized in the 3'→5' direction by coupling standard phosphoramidite monomers with an automated DNA synthesizer. Typically, 500 angstrom controlled-pore glass supports are used at the 0.2 micromole scale. After the desired probe sequence has been assembled (using A, G, C, and T monomers), hexaethylene oxide phosphoramidite monomer (Glen Research) is added to the 5' terminus. The coupling wait time is extended to 15 minutes by modifying the synthesizer program. Additional hexaethylene oxide monomer units are added in the same way. C-6 Amino phosphoramidite (Glen Research) is then added to the 5' terminus; the coupling wait time is again extended to 15 minutes. The acetic anhydride capping step and the final acidic detritylation step are eliminated. Capture probe sequences are cleaved from the solid support and deprotected with ammonium hydroxide, concentrated to dryness, precipitated in ethanol, and purified by reverse-phase

-19-

HPLC using an acetonitrile gradient in triethylammonium acetate buffer.

Example 4: Attachment of Capture Probes

The purified, amine-labeled capture probes from Example 3 are adjusted to a concentration of 500 micromolar in 100 mM sodium carbonate buffer (pH 9.0), and are applied to the derivatized glass surface from Example 2 at defined positions. For manual deposition, aliquots of 0.2 microliter each are applied with a pipetman. The array is incubated at room temperature in a moisture-saturated environment for at least two hours. The attachment reaction is terminated by immersing the glass surface in an aqueous 1% ammonia solution for five minutes with gentle agitation. The glass surface is then subjected to three 5-minute washes, using fresh portions of distilled water for each wash. The array is then soaked in 1 M phosphate buffered saline (PBS) solution for 2 hours at room temperature, then rinsed again for 5 minutes in distilled water.

15 Example 5: Surface Modification

The ammonia solution from Example 4 is replaced with a 1-5% aqueous solution of a different primary amine-containing molecule. A small amount (10%) of methanol or acetonitrile cosolvent is added, if necessary.

16 The glass surface is then subjected to three 5-minute washes, using
fresh portions of distilled water for each wash. The surface is soaked in 1 M
phosphate buffered saline (PBS) solution for 2 hours, then washed again for 5
minutes with distilled water. The glass surface is immersed in a dilute, aqueous
solution of a protein-containing blocking solution for several minutes, then
subjected to three 5-minute washes, using fresh portions of distilled water for
each wash. Finally, the surface is air dried.

-20-

Example 6: Fusion Hybridization

50 microliters of a solution containing the RNA-protein fusions and consisting of 25 mM Tris-HCl (pH 8.0) and 100 mM potassium chloride are applied to the glass microchip surface in a chamber that can contain and seal
5 the liquid. The solution is maintained at a specific temperature (determined by the capture oligo design) for at least three hours. Excess, non-hybridized RNA-protein fusions are removed by washing with 25 mM Tris-HCl (pH 8.0) and 50 mM potassium chloride for several minutes at the incubation temperature. The protein chip is subjected to two 15-minute washes, using a
10 buffer that is more stringent and contains a lower salt concentration than the buffer used for the hybridization reaction.

Example 7: Generation of an Exemplary FLAG and HA11 Fusion Chip

Using the techniques essentially as described above, exemplary FLAG and HA11 fusion chips were generated as follows.

15 For silylation of the glass microchip surface, pre-cleaned 1 x 3 inch glass microscope slides (Goldseal, #3010) were treated with Nanostrip (Cyantek) for 15 minutes, 10% aqueous NaOH at 70°C for 3 minutes, and 1% aqueous HCl for 1 minute, thoroughly rinsing with deionized water after each solution. The slides were then dried in a vacuum desiccator over anhydrous
20 calcium sulfate for several hours. A 1% solution of aminopropyltrimethoxysilane (Gelest, Inc.) in 95% acetone / 5% water was prepared and allowed to hydrolyze for 20 minutes. The glass slides were immersed in the hydrolyzed silane solution for 5 minutes with gentle agitation. Excess silane was removed by subjecting the slides to ten 5-minute washes,
25 using fresh portions of 95% acetone / 5% water for each wash, with gentle agitation. The slides were then cured by heating at 110°C for 20 minutes.

-21-

To derivatize with a homobifunctional linker, the silane treated slides were immersed in a freshly prepared 0.2% solution of phenylene 1,4-diisothiocyanate (Aldrich Chemical Co.) in 90% DMF / 10% pyridine for two hours, with gentle agitation. The slides were washed sequentially with
5 90% DMF / 10% pyridine, methanol, and acetone. After air drying, the functionalized slides were stored at 0°C in a vacuum desiccator over anhydrous calcium sulfate.

Capture oligos were then designed and synthesized by standard techniques. In particular, the RNA employed to make the FLAG epitope fusion
10 (17 amino acids total) consisted of 5'-r(UAA UAC GAC UCA CUA UAG GGA CAA UUA CUA UUU ACA AUU ACA AUG GAC UAC AAG GAC GAU GAC GAU AAG GGC GGC UGG UCC CAC CCC CAG UUC GAG AAG) (SEQ ID NO: 1). The RNA employed to make the HA11 epitope fusion (20 amino acids total) consisted of 5'-r(UAA UAC GAC UCA CUA UAG GGA CAA UUA CUA UUU ACA AUU ACA AUG UAC CCC UAC GAC GUG CCC GAC UAC GCC GGC GGC UGG UCC CAC CCC CAG UUC GAG AAG) (SEQ ID NO: 2). In addition, in each case, the following DNA linker, which also contained the essential puromycin moiety at its 3'-end, was ligated to the 3'-terminus of the RNA message:
15 5'-d(AAAAAAAAAAAAAAAAAAAAAAACC) (SEQ ID NO: 3).

Specific, non-interacting, and thermodynamically isoenergetic sequences along the target RNAs were identified to serve as capture points. The software program HybSimulator v2.2 (Advanced Gene Computing Technology, Inc.) facilitated the identification and analysis of potential capture
25 probes. A single specific capture probe for each RNA was ultimately identified (CPflag and CPha11). In addition, two sequences common to each RNA (CPt7, CPtag) were also identified to serve as positive controls. Four non-sense

-22-

sequences (CPau1, CPau5, CPirs, CPkt3) were generated as well to serve as negative controls. In total, eight unique sequences were selected. These oligonucleotides were prepared so that they could be attached to the chip surface at either the 3'- or 5'-terminus. Therefore, 16 capture probes were
5 prepared comprising eight unique sequences. The following is a list of these capture probe sequences (5' to 3') (SEQ ID NOS: 4-11):

	CPt7:	TGTAAATAGTAATTGTCCC
	CPtag:	CTTCTCGAACTGGG
	CPau1:	CCTGTAGGTGTCCAT
10	CPau5:	CAGGTAGAACGTCGGT
	CPflag:	CATCGTCCTTAGTC
	CPha11:	CGTCGTAGGGTA
	CPirs:	CCGCTCCTGATGTA
	CPkt3:	TCGGGAGGCATTG.

15 Oligonucleotide capture probes were chemically synthesized in the 3' to 5' direction by coupling standard phosphoramidite monomers using an automated DNA synthesizer (PE BioSystems Expedite 8909). Typically, 500 angstrom controlled-pore glass supports were used at the 0.2 micromole scale. In the case of 5'-attachment, after the desired probe sequence had been
20 assembled (using A, G, C, and T monomers), four hexaethylene oxide phosphoramidite monomers (Glen Research) were added to the 5'-terminus. The coupling wait time was extended to 15 minutes by modifying the synthesizer program. Additional hexaethylene oxide monomer units were added in the same way. C-6 Amino phosphoramidite (Glen Research) was then
25 added to the 5' terminus; the coupling wait time was again extended to 15

-23-

minutes. The acetic anhydride capping step and the final acidic detritylation were eliminated. In the case of 3'-attachment, oligonucleotide synthesis began with a controlled-pore glass support bearing orthogonally protected primary hydroxyl and amino functionalities (Glen Research). Chain elongation began
5 on the hydroxyl group, and the amino group remained protected during oligomer assembly, only being unveiled during the final deprotection. The first four monomers to be added were hexaethylene oxide units, followed by the standard A, G, C, and T monomers. All capture oligo sequences were cleaved from the solid support and deprotected with ammonium hydroxide,
10 concentrated to dryness, precipitated in ethanol, and purified by reverse-phase HPLC using an acetonitrile gradient in triethylammonium acetate buffer. Appropriate fractions from the HPLC were collected, evaporated to dryness in a vacuum centrifuge, and then coevaporated with a portion of water.

To attach the purified, amine-labeled capture oligos, the oligos were
15 adjusted to a concentration of 250 micromolar in 50 mM sodium carbonate buffer (pH 9.0) containing 10% glycerol. The oligos were then robotically applied (MicroGrid, BioRobotics) to the derivatized glass surface described above at defined positions in a 5 x 5 x 16 array pattern (384 spots) within a 20 x 20mm area. The layout of these capture probes is shown schematically in
20 Figure 3. A 16-pin tool was used to transfer the liquid, producing 200 micron features with a pitch of 600 microns. Each sub-grid of 24 spots represented a single capture probe (i.e., 24 duplicate spots). The array was incubated at room temperature in a moisture-saturated environment for 12-18 hours. The attachment reaction was terminated by immersing the glass surface in an
25 aqueous 1% ammonia solution for five minutes with gentle agitation. The glass surface was then subjected to three 5-minute washes, using fresh portions of distilled water for each wash. The array was then soaked in a 10X PBS

-24-

(phosphate buffered saline) solution for 2 hours at room temperature, and then rinsed again for 5 minutes in distilled water.

RNA-protein fusions between the peptides containing the FLAG and HA11 epitopes and their corresponding mRNAs were produced as generally described by Szostak et al., WO 98/31700; and Roberts and Szostak, Proc. Natl. Acad. Sci. USA 94:12297-12302, 1997. The polymerase chain reaction using Taq polymerase (Promega) was used to amplify the sequences 5'-TAA TAC GAC TCA CTA TAG GGA CAA TTA CTA TTT ACA ATT ACA ATG GAC TAC AAG GAC GAT GAC GAT AAG GGC GGC TGG TCC CAC CCC CAG TTC GAG AAG (SEQ ID NO: 12) and 5'-TAA TAC GAC TCA CTA TAG GGA CAA TTA CTA TAG GGA CAA TTA CTA TTT ACA ATT ACA ATG TAC CCC TAC GAC GTG CCC GAC TAC GCC GGC GGC TGG TCC CAC CCC CAG TTC GAG AAG (SEQ ID NO: 13) for FLAG and HA11, respectively, using the oligonucleotide primers 5'-TAA TAC GAC TCA CTA TAG GGA CAA TTA CTA TTT ACA ATT (SEQ ID NO: 14) and 5'-AGCGGATGCCTCTCGAACTGGGGTGGGA (SEQ ID NO: 15). The resulting PCR products were transcribed in vitro using T7 RNA polymerase (Ambion) to produce an mRNA containing the coding region for the FLAG and HA11 epitopes and the TMV untranslated region. This RNA was ligated to a DNA linker 5'-AAA AAA AAA AAA AAA AAA AAA AAA CC (SEQ ID NO: 3) containing a 5' phosphate and a 3' puromycin by T4 DNA ligase (Promega) in the presence of an 80:20 mixture of the following two DNA splints: 5'-TGCAACGACCAACTTTTTTTAGCGCATGC (SEQ ID NO: 16) and 5'-TGCAACGACCAACTTTTTTTNAGCGCATGC (SEQ ID NO: 17), each containing two biotin moieties at the 5' terminus. The resulting RNA-DNA chimera was purified by binding to Immobilized NeutrAvidin (Pierce), washing to remove unligated material, and eluting by displacement

-25-

using the sequence 5'-GCATCCGCTAAAAAAAAAGTTGGTCGTTGC (SEQ ID NO: 18). Subsequent translations were performed in rabbit reticulocyte lysate (Ambion) according to the manufacturer's instructions except that MgCl₂ (150 mM) and KCl (425 mM) were added after 30 minutes

5 to promote the formation of the puromycin-peptide bond. The RNA-peptide fusions were then purified by oligo dT affinity chromatography (Pharmacia), quantitated by scintillation counting of the incorporated vs. added ³⁵S methionine (Amersham), and concentrated to a low volume via membrane filtration (MicroCon).

10 For hybridization of the fusions to the immobilized capture probes, aliquots of each of the FLAG and HA11 fusions, corresponding to 1.0 picomole each, were combined and adjusted to 5X SSC (saline sodium citrate) + 0.02% Tween-20 in a volume of 20 microliters. The solution was applied to the glass chips described above, coverslips were placed on top, and the slides were

15 placed in a moisture-saturated chamber at room temperature. After 18 hours the coverslips were removed, and the slides were washed sequentially with stirred 500 mL portions of 1X SSC + 0.02% Tween-20, 1X SSC + 0.02% Tween-20, and 1X SSC for 5 minutes each, followed by a brief rinse with 0.2X SSC. After removal of liquid the slides were allowed to briefly air-dry.

20 To detect hybridization, the FLAG and HA11-fusion chip was exposed to a phosphorimage screen (Molecular Dynamics) for 60 hours by direct contact between the screen and the chip. This allowed identification of the areas that contained hybridized fusions, since the peptides contained a ³⁵S methionine radiolabel which was detectable by the phosphor storage screen.

25 As shown in Figure 4, analysis of the phosphorimage revealed that the fusions had successfully hybridized to their respective capture probes targeting specific areas of the RNA message (i.e., CPflag and CPha11). In addition, the four

-26-

non-sense capture probes, which were not complementary to any region of the FLAG or HA11 RNA, did not give any appreciable signal (i.e., CPau1, CPau5, CPirs, CPkt3). The positive control capture probe CPtag produced the expected signal, but the corresponding positive control capture probe CPt7 did

5 not, likely due to degradation (e.g., exonuclease contamination) of the 5'-region of the targeted RNA. These results demonstrated the feasibility of addressing a mixture of peptides (as fusions) to specific locations on the surface of a chip. Both the 3'-attached capture probes and the 5'-attached capture probes were effective.

10 A duplicate chip was probed with a monoclonal antibody that recognized the HA11 epitope. All of the following steps were performed at 4°C. Nonspecific sites were first blocked with a solution containing 1X PBS (phosphate buffered saline) + 1% BSA (bovine serum albumin, RNase free grade, Ambion) + 0.02% Tween-20 for 1 hour under a coverslip. The blocking
15 solution was removed and 50 microliters of HA.11 monoclonal antibody (100:1 dilution, Berkeley Antibody Co.) in 1X PBS + 0.02% Tween-20 was applied to the chip under a coverslip. After 2 hours the coverslip was removed, and the chip was washed with three 50mL portions of 1X PBS + 0.02% Tween-20 for 5 minutes each, with gentle agitation. Excess liquid was removed and then 50
20 microliters of Cy3-labeled goat anti-mouse IgG (400:1 dilution, Amersham Pharmacia Biotech) in 1X PBS + 0.02% Tween-20 was added under a coverslip. After 1 hour the coverslip was removed, and the chip was washed in three 50mL portions of 1X PBS + 0.02% Tween-20 for 5 minutes each, with gentle agitation. Excess liquid was removed, and the chip was allowed to
25 air-dry at room temperature. The chip was subsequently analyzed at 10 micron pixel resolution with a confocal laser scanner (ScanArray 3000, General Scanning) using preset excitation and emission wavelengths tuned to the Cy3

-27-

fluorophore. As shown in Figure 5, the resulting fluorimage was in accord with the phosphorimage and demonstrated that the HA11 peptide, which was covalently linked to its RNA message and fixed to the chip surface, was functional and was available to interact with its binding partner (the HA11 monoclonal antibody). Moreover, although both the FLAG-fusion and the HA11-fusion were presented on the chip surface, the HA11 monoclonal antibody was specific for its own epitope. In addition, the 3'-attachment capture probes generally provided a better signal than the 5'-attachment capture probes. Without being bound to a particular theory, this may reflect the greater accessibility of the epitope when it is oriented away from the chip surface.

Example 8: Generation of an Exemplary Myc Fusion Chip

Using the techniques essentially as described above, an exemplary Myc fusion chip was also generated as follows.

For silylation of the glass surface, select grade, low-iron content, 15 pre-cleaned 25 x 75mm glass microscope slides (VWR Scientific, #48311-950) were used as supplied. A 1% solution of aminopropyltrimethoxysilane (Gelest, Inc.) in 95% acetone / 5% water was prepared and allowed to hydrolyze for 20 minutes. The glass slides were immersed in the hydrolyzed silane solution for 5 minutes with gentle agitation. Excess silane was removed by subjecting the 20 slides to ten 5-minute washes, using fresh portions of 95% acetone / 5% water for each wash, with gentle agitation. The slides were then cured by heating at 110°C for 20 minutes.

To derivatize with a homobifunctional linker, the silane treated slides were immersed in a freshly prepared 0.2% solution of phenylene 25 1,4-diisothiocyanate (Aldrich Chemical Co.) in 90% DMF / 10% pyridine for two hours, with gentle agitation. The slides were washed sequentially with

-28-

90% DMF / 10% pyridine, methanol, and acetone. After air drying, the functionalized slides were stored at 0°C in a vacuum desiccator over anhydrous calcium sulfate.

The capture oligos were synthesized based on the Myc sequence. In 5 particular, the RNA employed to make the c-myc fusion (33 amino acids total) consisted of the following sequence:

5'-r(UAAUACGACUCACUAUAGGGACAUUACUAUUACAAUUACA
AUGGGGACAAUUACUAUUACAAUUACAAUGGCUGAAGAACAGA
AACUGAUCUCUGAAGAAGACCUGCUGCGUAAACGUCGUGAACAGC
10 UGAAACACAAACUGGAACAGCUGCGUAACUCUUGCGCU) (SEQ ID NO: 19). In addition, the following DNA linker, which also contains the essential puromycin moiety, was ligated to the 3'-terminus of the RNA message: 5'-d(AAAAAAAAAAAAAAAAAAAAAAAAACC) (SEQ ID NO: 3). Three non-overlapping and thermodynamically isoenergetic 20-mer sequences along the RNA were identified to serve as capture points. In 15 addition, dA25 (on the ligated DNA) was selected as a fourth target area. The targeted sequences began at nucleotide positions 1, 33, 80, and 125 (CP01, CP33, CP80 and CP125, respectively). A mismatch sequence, derived from target sequence 33 and containing four internal and adjacent nucleotide mismatches, was also designed (CPmm). A non-sense sequence, corresponding 20 to the reverse-orientation of CP33, was also utilized as a negative control (CPns). The following is a list of the capture probe sequences that were employed (5' to 3') (SEQ ID NOS: 20-25):

CP01: TTGTAAATAGTAATTGTCCC
25 CP33: AGAGATCAGTTCTGTTCTT
CP80: AGTTTGTGTTTCAGCTGTT

-29-

CP125: TTTTTTTTTTTTTTTTTTTTTTTTT

Cpmm: AGAGATCTCAATCTGTTCTT

Cpns: TTCTTGTCCTTGACTAGAGA

Oligonucleotide capture probes were chemically synthesized in the 3' 5 to 5' direction by coupling standard phosphoramidite monomers with an automated DNA synthesizer (PE BioSystems Expedite 8909). Typically, 500 angstrom controlled-pore glass supports were used at the 0.2 micromole scale. After the desired probe sequence had been assembled (using A, G, C, and T monomers), hexaethylene oxide phosphoramidite monomer (Glen Research) 10 was added to the 5'-terminus. The coupling wait time was extended to 15 minutes by modifying the synthesizer program. Additional hexaethylene oxide monomer units were added in the same way. C-6 Amino phosphoramidite (Glen Research) was then added to the 5' terminus; the coupling wait time was again extended to 15 minutes. The acetic anhydride capping step and the final 15 acidic detritylation were eliminated. Capture oligo sequences were cleaved from the solid support and deprotected with ammonium hydroxide, concentrated to dryness, precipitated in ethanol, and purified by reverse-phase HPLC using an acetonitrile gradient in triethylammonium acetate buffer. Appropriate fractions from the HPLC were collected, evaporated to dryness in 20 a vacuum centrifuge, and then coevaporated with a portion of water.

To attach these purified, amine-labeled capture oligos, the oligos were adjusted to a concentration of 500 micromolar in 100 mM sodium carbonate buffer (pH 9.0) and were applied to the derivatized glass surface at defined positions in a 6 x 6 array pattern (36 spots) within a 20 x 20mm area 25 (as shown in Figure 6). CP01 was applied to locations A1, B1, C1 and A4, B4, C4. CP33 was applied to locations D1, E1, F1 and D4, E4, F4. CP80 was

-30-

applied to locations A2, B2, C2 and A5, B5, C5. CP125 was applied to locations D2, E2, F2 and D5, E5, F5. Cpmm was applied to locations A3, B3, C3 and A6, B6, C6. Cpns was applied to locations D3, E3, F3 and D6, E6, F6. For manual deposition, aliquots of 0.2 microliter each were applied with a

5 pipetman. The array was incubated at room temperature in a moisture-saturated environment for 12-18 hours. The attachment reaction was terminated by immersing the glass surface in an aqueous 1% ammonia solution for five minutes with gentle agitation. The glass surface was then subjected to three 5-minute washes, using fresh portions of distilled water for each wash.

10 The array was then soaked in a 10X PBS (phosphate buffered saline) solution for 2 hours at room temperature, and then rinsed again for 5 minutes in distilled water.

RNA-protein fusions between a 33 amino acid peptide containing the c-myc epitope and its mRNA were produced as described by Szostak et al.,

15 WO 98/31700; and Roberts and Szostak, Proc. Natl. Acad. Sci. USA 94:12297-12302, 1997. The polymerase chain reaction using Taq polymerase (Promega) was used to amplify the sequence 5'-AGC GCA AGA GTT ACG CAG CTG TTC CAG TTT GTG TTT CAG CTG TTC ACG ACG TTT ACG CAG CAG GTC TTC TTC AGA GAT CAG TTT CTG TTC TTC AGC CAT (SEQ ID NO: 26) using oligonucleotide primers 5'-AGC GCA AGA GTT ACG CAG CTG (SEQ ID NO: 27) and 5'-TAA TAC GAC TCA CTA TAG GGA CAA TTA CTA TTT ACA ATT ACA ATG GCT GAA GAA CAG AAA CT (SEQ ID NO: 28). The resulting PCR product was transcribed in vitro using T7 RNA polymerase (Ambion) to produce an mRNA containing the coding region for

20 the c-myc epitope and the TMV untranslated region. This RNA was ligated to a DNA linker 5'-AAA AAA AAA AAA AAA AAA AAA AAA CC (SEQ ID NO: 3) containing a 5' phosphate and a 3' puromycin by T4 DNA

25

-31-

ligase (Promega) in the presence of a DNA splint with the sequence TTT TTT
5 TTT TAG CGC AAG A (SEQ ID NO: 29). The resulting 154mer RNA-DNA
chimera was purified by denaturing polyacrylamide gel electrophoresis (6%
acrylamide). Translation was performed in rabbit reticulocyte lysate (Ambion)
10 according to the manufacturer's instructions except that KCl (500 mM) was
added after 30 minutes to promote the formation of the puromycin-peptide
bond. The RNA-peptide fusion was purified by oligo dT affinity
chromatography (Pharmacia), quantitated by scintillation counting of the
incorporated vs. added 35 S methionine (Amersham), and dried to a pellet. 2.5
15 pmol of the c-myc fusion was produced.

To hybridize to the capture probes, the dry myc-fusion pellet was
taken up with 20 microliters of 5X SSC (saline sodium citrate) + 0.02% SDS,
mixed, and then briefly centrifuged. The solution was applied to the slide
described above, a coverslip was placed on top, and the slide was placed in a
15 moisture-saturated chamber at room temperature. After 18 hours the coverslip
was removed, and the slide was washed sequentially with stirred 500 mL
portions of 5X SSC + 0.02% SDS, 2.5X SSC + 0.01% SSC, 2.5X SSC, and
1.25X SSC for 5 minutes each. After removal of liquid the slide was allowed
to briefly air-dry.

20 To detect hybridization of the Myc fusions, the glass chip was
exposed to a phosphorimage screen (Molecular Dynamics) for four hours by
direct contact between the screen and the chip. This allowed identification of
the areas that contained hybridized myc-fusion, since the myc peptide
contained a 35 S methionine radiolabel which was detectable by the phosphor
25 storage screen. As shown in Figure 7, analysis of the phosphorimage revealed
that the myc-fusion had successfully hybridized to each of the four capture
probes that targeted the myc RNA message and DNA linker sequence. In

-32-

addition, the non-sense capture probe, which was not complementary to any region of the myc RNA, did not give any appreciable signal. The capture probe sequence that contained several mismatches produced only a small amount of signal. These results demonstrated that it was possible to address a peptide (as
5 a fusion) to a specific location on the surface of a chip.

After phosphorimage analysis, the same chip was probed with a monoclonal antibody that recognized the c-myc epitope. All of the following steps were performed at 4°C. Nonspecific sites were first blocked with a solution containing 1X PBS (phosphate buffered saline) + 1% BSA (bovine
10 serum albumin, Sigma Chemical Co.) + 0.1 unit per microliter RNase inhibitor (Ambion) for 1 hour under a coverslip. The blocking solution was removed, and 50 microliters of 9E10 monoclonal antibody in 1X PBS (400:1 dilution, Berkeley Antibody Co.) was applied to the chip under a coverslip. After 1 hour the coverslip was removed, and the chip was washed with three 50mL portions
15 of 1X PBS for 5 minutes each, with gentle agitation. Excess liquid was removed, and then 50 microliters of Cy3-labeled goat anti-mouse IgG in 1X PBS (400:1 dilution, Amersham Pharmacia Biotech) was added under a coverslip. After 1 hour the coverslip was removed, and the chip was washed in three 50mL portions of 1X PBS for 5 minutes each, with gentle agitation.
20 Excess liquid was removed, and the chip was allowed to air-dry at room temperature. The chip was subsequently analyzed at 10 micron pixel resolution with a confocal laser scanner (ScanArray 3000, General Scanning) using preset excitation and emission wavelengths tuned to the Cy3 fluorophore. As shown in Figure 8, the resulting fluorimage was in accord with the phosphorimage and
25 demonstrated that the myc peptide, which was covalently linked to its RNA message and fixed to the chip surface, was functional and was available to interact with its binding partner (the monoclonal antibody).

All publications and patents mentioned in this specification are herein incorporated by reference to the same extent as if each individual publication or patent was specifically and individually indicated to be incorporated by reference.

5

Other Embodiments

From the foregoing description, it will be apparent that variations and modifications may be made to the invention described herein to adopt it to various usages and conditions. Such embodiments are also within the scope of the following claims.

10

What is claimed is:

-34-

Claims

1. A solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound.
2. A solid support comprising an array of immobilized capture probes, wherein each of said capture probes is attached to the surface of said solid support through a non-nucleosidic spacer group, and wherein each of said capture probes comprises an oligonucleotide sequence to which a nucleic acid-10 protein fusion is bound.
3. A solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a ribosome display particle is bound.
4. The solid support of claim 1, 2, or 3, wherein said nucleic acid-15 protein fusion is an RNA-protein fusion.
5. The solid support of claim 1, 2, or 3, wherein said capture probe is bound to said nucleic acid-protein fusion by base pairing.
6. The solid support of claim 1, 2, or 3, wherein said protein is encoded by said nucleic acid.
- 20 7. The solid support of claim 1, 2, or 3, wherein said spacer group

-35-

comprises a polyalkylene oxide, polyethylene oxide, or hexaethylene oxide.

8. The solid support of claim 1, 2, or 3, wherein said capture probe comprises a photocleavable linker.

9. The solid support of claim 1, 2, or 3, wherein said oligonucleotide sequence comprises a modified base, an internucleotide analog, or a carbohydrate modification.

10. The solid support of claim 9, wherein said modified base is 5-propyne pyrimidine, said internucleotide analog is a 3'-phosphoramidate linkage, or said carbohydrate modification is a 2'-O-methyl group.

11. The solid support of claim 1, 2, or 3, wherein said nucleic acid-protein fusion comprises a hybridization tag sequence.

12. The solid support of claim 11, wherein said hybridization tag sequence comprises a modified base, an internucleotide analog, or a carbohydrate modification.

13. The solid support of claim 1, 2, or 3, wherein said capture probe further comprises a reactive moiety.

14. The solid support of claim 13, wherein said reactive moiety is a primary amino group.

15. The solid support of claim 1, 2, or 3, wherein said solid support

-36-

is a glass or silica-based chip.

16. The solid support of claim 1, 2, or 3, wherein said nucleic acid-protein fusion is covalently linked to said capture probe.

17. The solid support of claim 16, wherein said capture probe
5 comprises one or more psoralen moieties.

18. A method for preparing a solid support, said method comprising
the steps of:

- (a) preparing a capture probe by linking a spacer group to an oligonucleotide sequence;
- 10 (b) attaching said capture probe to said solid support; and
- (c) binding a nucleic acid-protein fusion to said capture probe.

19. A method for preparing a solid support, said method comprising
the steps of:

- (a) attaching a spacer group to a surface of said solid support;
- 15 (b) attaching a bifunctional linker to said spacer group;
- (c) attaching a capture probe to said bifunctional linker; and
- (d) binding a nucleic acid-protein fusion to said capture probe.

20. The method of claim 18 or 19, wherein said nucleic acid-protein fusion is an RNA-protein fusion.

20 21. A method for detecting an interaction between a protein and a compound, said method comprising the steps of:

-37-

- (a) providing a solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion is bound;
- 5 (b) contacting said solid support with a candidate compound under conditions which allow an interaction between the protein portion of said nucleic acid-protein fusion and said compound; and
 - (c) analyzing said solid support for the presence of said compound as an indication of an interaction between said protein and said compound.
- 10 22. A method for detecting an interaction between a protein and a compound, said method comprising the steps of:
 - (a) providing a population of nucleic acid-protein fusions;
 - (b) contacting said population of nucleic acid-protein fusions with a candidate compound under conditions which allow an interaction between the protein portion of said nucleic acid-protein fusion and said compound;
 - 15 (c) contacting the product of step (b) with a solid support comprising an array of immobilized capture probes, each of said capture probes comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which a nucleic acid-protein fusion binds; and
 - (d) analyzing said solid support for the presence of said compound as an indication of an interaction between said protein and said compound.
- 20 23. The method of claim 21 or 22, wherein said nucleic acid-protein fusion is an RNA-protein fusion.
- 24. The method of claim 21 or 22, wherein said compound is

labeled.

25. The method of claim 21 or 22, wherein said compound is a protein, a therapeutic, an enzyme, or a nucleic acid.

26. An array of nucleic acid-protein fusions, said array comprising
5 at least 10^2 different fusions/cm².

27. The array of claim 26, wherein said array comprises at least 10^4 different fusions/cm².

28. The array of claim 26, wherein said nucleic acid-protein fusions are RNA-protein fusions.

10 29. A method for generating an addressable array of molecules, said method comprising:

(a) providing a solid support on which an array of nucleic acid molecules is immobilized;

15 (b) contacting said solid support with a population of addressable molecules; and

(c) allowing said addressable molecules to orient themselves on said solid support by sequence-dependent recognition and binding of said immobilized nucleic acid molecules.

30. The method of claim 29, wherein said addressable array of
20 molecules is an array of nucleic acid-protein fusions.

-39-

31. The method of claim 30, wherein said nucleic acid-protein fusions are RNA-protein fusions.

32. The method of claim 29, wherein said sequence-dependent recognition and binding comprises base pairing.

5 33. The method of claim 29, wherein said solid support is a glass or silica-based chip.

10 34. The method of claim 29, wherein said nucleic acid molecules immobilized on said solid support are capture probes, each comprising a non-nucleosidic spacer group and an oligonucleotide sequence to which said addressable molecule binds.
